Global Road Safety Insights

Synthesis from the ESRA3 survey across 39 countries

Partners in the ESRA3 survey

ESRA coordination

- Vias institute, Belgium: *Uta Meesmann, Naomi Wardenier, Sophie Vanhove, Simon Laurant*

ESRA3 steering group partners

- BAST - Federal Highway Research Institute, Germany: *Fabian Surges, Anna Marie Harkin*
- DTU - Technical University of Denmark, Division of Transportation Science, Denmark: *Mette Møller, Thomas Christian Jensen*
- IATSS - International Association of Traffic and Safety Sciences, Japan: *Hideki Nakamura, Minoru Makuta, Yutaka Ohno*
- ITS - Motor Transport Institute, Poland: *Dagmara Jankowska-Karpa*
- KFV - Austrian Road Safety Board, Austria: *Gerald Furian, Susanne Kaiser*
- NTUA - National Technical University of Athens, Greece: *George Yanniss, Alexandra Laiou, Dimitrios Nikolaou, Konstantinos Kaselouris*
- PRP - Portuguese Road Safety Association, Portugal: *Alain Areal, José Trigo, Carlos Pires*
- SWOV - Institute for Road Safety Research, Netherlands: *Agnieszka Stelling*
- TIRF - Traffic Injury Research Foundation, Canada: *Craig Lyon, Ward Vanlaar, Robyn Robertson, Karen Bowman, Steve Brown, Milad Delavary*
- University Gustave Eiffel, France: *Marie-Axelle Granié, Brice Douffet, Aline Alauzet, Patricia Champelovier, Frédéric Martinez*

ESRA3 national/regional partners

- AAAFTS - AAA Foundation for Traffic Safety, USA: *Rebecca Steinbach*
- ATRANS - Asian Transportation Research Society, Thailand: *Tuenjai Fukuda*
- ORS/DITRDCA - Office of Road Safety, Department of Infrastructure, Transport, Regional Development, Communications and the Arts, Australia: *Joanne Wilson-Ridley*
- AVP - Slovenian Traffic Safety Agency, Slovenia: *Saša Jevšnik Kafol*
- BFU - Swiss Council for Accident Prevention, Switzerland: *Yvonne Achermann Stürmer*
- CDV - Transport Research Centre, Czech Republic: *Pavlna Skládaná*
- CTL - Research Centre for Transport and Logistics, Italy: *Davide Shingo Usami, Luca Persia, Francesca Damiani*
- Department for Transport, United Kingdom: *Matthew Tranter*
- DGT - Traffic General Directorate, Ministry of Interior, Spain: *Patricia Fernandez, Alvaro Gómez Mendez*
- Liikenneturva - Finnish Road Safety Council, Finland: *Marja Pakarinen, Leena Poysti*
- Fundación MAPFRE, Spain: *Jesús Monclús, Jorge Ortega*
- NRSA - Israel National Road Safety Authority, Israel: *Yiftach Gordoni-Lavy*
- RSA - Road Safety Authority, Ireland: *Velma Burns, Sharon Heffernan*
- RTSA - Road Traffic Safety Agency, Republic of Serbia: *Bojana Miljković, Milica Dragišić, Mladen Kovač*
- RTSD - Road traffic safety directorate, Latvia: *Juris Kreicbergs, Aivars Aksenoks*
- The Ministry of Mobility and Public Works, Luxembourg: *Alain Disiviscour, Nadine Di Letizia*
- VTI - Swedish National Road and Transport Research Institute, Sweden: *Anna Vadeby, Gunilla Sörensen*
- WHO - WHO Regional Office for Europe, Germany: *Jonathon Passmore*

Acknowledgement

Vias institute, which coordinates the ESRA initiative, would like to thank all 28 participating organisations for supporting and financing the national ESRA3 surveys in 39 countries in 2023, but also for their enthusiastic commitment, flexibility, and cooperative attitude. We would also like to express our gratitude to the ten other members of the ESRA3 steering group (BAST (Germany), DTU (Denmark) IATSS (Japan), University Gustave Eiffel (France), ITS (Poland), KfV (Austria), NTUA (Greece), PRP (Portugal), SWOV (the Netherlands), TIRF (Canada)) for helping to develop the ESRA3 survey and the common ESRA3 outputs. Special thanks go to Carlos Pires for his assistance in producing the standardized tables and graphs and to Gerald Furian and Aggelos Soteropoulos for reviewing this Main Report.

ESRA is funded through the contributions of the partner organisations, either from their own resources or from sponsoring. Fundación MAPFRE sponsored as regional partner six Latin American countries and the WHO Regional Office for Europe six additional European/Asian countries. Part of the funding for Vias institute is provided by the Belgian Federal Public Service Mobility & Transport.

Executive summary

The ESRA initiative

ESRA (E-Survey of Road users' Attitudes) is a joint initiative of road safety institutes, research centres, public services, and private sponsors from all over the world. The aim is to collect and analyse comparable data on road safety performance and road safety culture. The ESRA data are used as a basis for a large set of road safety indicators. These provide scientific evidence for policy making at national and international levels.

Vias institute in Brussels (Belgium) initiated and coordinates ESRA, in cooperation with ten steering group partners (BASt (Germany), DTU (Denmark), IATSS (Japan), ITS (Poland), KfV (Austria), NTUA (Greece), PRP (Portugal), SWOV (the Netherlands), TIRF (Canada), University Gustave Eiffel (France)).

Since 2015, the ESRA survey was already conducted in 68 countries across the world. More than 40 partner organizations contributed to this achievement. Already three editions of the ESRA survey have been launched (ESRA1: 2015-2018; ESRA2: 2018-2021; ESRA3: 2022-2024). The fieldwork of the third edition (ESRA3) was conducted simultaneously in 39 countries in 2023. This edition was supported by 29 partner organizations across six continents. ESRA is funded through the contributions of the partner organisations, either from their own resources or through sponsoring.

Study design and scope of the questionnaire

ESRA data are collected through online panel surveys, using a representative sample of the national adult populations in each participating country (aiming at n=1000 per country). A few exceptions exist¹. At the heart of this survey is a jointly developed questionnaire, which was translated into 49 national language versions in ESRA3. The themes covered include self-declared behaviour, attitudes and opinions on unsafe traffic behaviour, enforcement experiences and support for policy measures. The survey addresses different road safety topics (e.g., driving under the influence of alcohol, drugs and medicines, speeding, distraction) and targets car occupants, moped riders and motorcyclists, cyclists, pedestrians, and riders of e-scooters. In ESRA3 the questions related to vulnerable road users (moped riders and motorcyclists, cyclists, pedestrians, and riders of e-scooters) have been expanded and questions on e-scooters and infrastructure have been added. The median length of the interview was 23 minutes.

Hard quota are used for gender and age² distribution during the sampling procedure (United Nations Statistics Division, 2023). The geographical spread of the sample across the country was at least monitored (soft quota). Three market research agencies (Dynata, Ipsos and Punto de Fuga) organised the fieldwork under the supervision of Vias institute. The fieldwork was conducted simultaneously in all 39 participating countries between May and September 2023.

Data processing and quality control

In order to maximise the cross-national comparability of the data, the programming of the survey, the data collection in all countries, and the data processing were centrally organized by Vias institute and the ESRA steering group. PRP (Portugal), in collaboration with Vias institute (Belgium), was responsible for the quality control of the standardized data cleaning and data processing procedure, as well as the extraction of standardized figures which were used in all common ESRA3 outputs. The national partners were asked to validate the national datafiles and the country fact sheets, before common output was published.

¹ In four countries, the targeted sample size had to be reduced to 500 respondents due to limitations of the national panel or too high costs (Armenia, Kyrgyzstan, Luxembourg, and Uzbekistan). In three countries the data was collected through another method (Armenia, Kyrgyzstan, and Uzbekistan).

² Six age groups: 18-24y, 25-34y, 35-44y, 45-54y, 55-64y, 65-74y.

Sample characteristics & fieldwork

In total, the ESRA3 survey collected data from more than 37000 road users across 39 countries. The samples (after applying a weighting factor) are representative for the national adult population according to interlaced quota of gender and six age groups (United Nations Statistics Division, 2023). Details on national results can be found in Appendix 6.

Key output

The key results of the ESRA3 survey were published through a series of reports including this main report, a methodology report, 13 thematic reports, the ESRA3 dashboard and 39 country fact sheets. In the country fact sheets national key results are compared to a regional mean (benchmark) and in the ESRA3 dashboard all national means of key results can be compared with other countries or regions. Comparisons over time, will be included in a dedicated report in 2025.

ESRA3 data was used by ESRA partners in a variety of ways, directly disseminating ESRA results (scientific publications, conference presentations, promotion through national reports, press releases and press conferences, social media posts, website entries, newsletter items, etc.). But partners made also use of ESRA3 data for deriving road safety policies and recommending measures as well as enriching other projects and activities.

All common ESRA3 output has been peer-reviewed within the consortium, following a pre-defined quality control procedure. Results and news on the ESRA initiative can be freely consulted and downloaded at the ESRA website (www.esranet.eu). For more information on quality control procedure see the detailed methodology report (Meesmann & Wardenier, 2024).

Conclusions

The initial aim of ESRA was to develop a system for gathering reliable and comparable information about people's attitudes towards road safety in several European countries. This objective has been achieved and the initial expectations have even been exceeded. ESRA has become a global initiative which already conducted surveys in more than 60 countries across six continents. The outputs of the ESRA project have become building blocks of national and international road safety monitoring systems such as the Global Status Report on Road Safety (GSRRS) of the WHO (World Health Organization, 2023), the country profiles (European Commission, 2024a) and thematic reports (European Commission, 2024b) of the European Road Safety Observatory (ERSO) of the European commission (European Commission, 2024c). The ESRA project has also demonstrated the feasibility and the added value of joint data collection on road safety attitudes and performance by partner organizations in a large number of countries. The intention is to repeat this survey every three to four years, retaining a core set of questions in every edition to allow the development of time series on road safety performance and road safety culture. The data collection of the next edition (ESRA4) will be organized between May and June 2026. Organisations interested in joining the ESRA initiative and becoming a national or regional partner can contact the ESRA Secretariat at ESRA@vias.be.

1 Background

1.1 Monitoring road safety attitudes and performance

Trends in road safety performance and the success of policy measures can be monitored using road safety performance indicators, based on accident statistics, roadside observations, or (questionnaire) surveys.

There is a broad consensus amongst road safety experts that roadside observations are the golden standard to produce road safety performance indicators since they are based on observed behaviour in traffic. But observation-based studies have also limitations. The number and nature of variables that are observable are limited. Furthermore, roadside observations require a sophisticated study design and protocol. They are very time intensive and cost consuming. At present, moreover, due to methodological differences, results of such studies are often not comparable across countries.

An alternative is to use questionnaire surveys. Such surveys, when properly designed and with an adequate sampling approach, can yield very useful information on road safety performance and road safety culture as well. Moreover, when online panels are used, such surveys appear to be a relatively inexpensive way for obtaining indicators on safety practice and road users' behaviour. Hence, surveys can be used to collect road safety indicators for benchmarking purposes.

1.2 The added value of using road safety surveys (questionnaires)

An important advantage of using road safety surveys (questionnaires) is that they allow to collect data on many additional topics and themes, as they are not limited to things which can be observed.

They offer the possibility to include variables that are related to certain behaviour. For example, they can provide insights into the socio-cognitive determinants of behaviour: attitudes, perceived social norm, risk perception, or existing habits. Socio-cognitive factors can help to understand the underlying motivations of certain behaviour (e.g. Ajzen, 1991; Rogers, 1975; Rosenstock, 1974; Vanlaar & Yannis, 2006). In the current literature those factors are often closely linked with assessing road safety culture (e.g., N. J. Ward et al., 2019).

Several of these socio-cognitive constructs are interesting in their own right, because they can help target policy and campaigns. Moreover, many other types of questions can be included that are related to road safety practice and culture, such as mobility behaviour, involvement in road crashes, support for policy measures, experience with enforcement, etc.. Also for these variables using a consistent design and questionnaire is important, to assure international comparability.

1.3 International comparability of data from road safety surveys

The results of national road safety surveys are rarely comparable across countries because of differences in aims, scope, methodology, questions used, or sample population being surveyed. Therefore, in 1991 the European Commission initiated the European project SARTRE (Social Attitudes to Road Traffic Risk in Europe (Cestac & Delhomme, 2012)). A common questionnaire and study design were developed, and face-to-face interviews were conducted among a representative sample of the national adult population in several European countries. Four editions of the SARTRE survey were completed (1991, 1996, 2002, 2010). In the first three editions of the SARTRE project, surveys were directed only to car drivers. In the fourth edition, the target group was extended to powered two-wheelers, pedestrians, cyclists, and users of public transport (Cestac & Delhomme, 2012). SARTRE4 involved 19 European countries. It was the last of the SARTRE series that was funded by the European Commission.

In 2015, Vias institute launched the ESRA (E-Survey of Road users' Attitudes) initiative to build on the SARTRE experience and extend scope and coverage, initially with partners from a number of EU countries. In a few years, the project evolved into a global initiative. Already three editions of ESRA have taken place between 2015 and 2023, with a total of 68 countries who participated in at least one of the ESRA editions. Overall, the ESRA initiative has demonstrated the feasibility and the added value of joint data collection on road safety attitudes and performance by partner organizations in many countries across the world.

2 Key outlines of ESRA3

2.1 Aim and objectives

ESRA (E-Survey of Road users' Attitudes) is a joint initiative of road safety institutes, research centres, public services, and private sponsors from all over the world. The aim is to collect and analyse comparable data on road safety performance and road safety culture. The ESRA data are used as a basis for a large set of road safety indicators. These provide scientific evidence for policy making at national and international levels.

The main objectives of the ESRA initiative can be summarized as follows:

- Provide scientific support for road safety policy at national and international levels.
- Make internationally comparable data available on the current road safety situation in countries all over the world.
- Develop a series of reliable, cost-effective and comparable road safety performance indicators.
- Develop time series on road safety performance.

The intention is to repeat this survey every three to four years and extend it to an increasing number of countries.

2.2 Consortium and evolution

The ESRA initiative was initiated by Vias institute (Belgium) in 2015 (Torfs et al., 2016). Three editions of the ESRA survey have already been conducted and data was collected in a total of 68 countries across six continents. The number of countries is still growing.

Figure 1 gives an overview of the geographical coverage of the three ESRA editions (2015-2023).

Figure 1: Evolution and geographic coverage of the different ESRA editions (2015-2023)

The first edition of the ESRA survey (ESRA1) was carried out in three waves (2015, 2016, 2017) and collected data from almost 40000 road users in 38 countries across five continents (Meesmann et al., 2018). The second edition (ESRA2) was conducted in two waves (2018, 2019-2020) and collected data from more than 45000 road users in 48 countries across six continents (Meesmann et al., 2022). In the most recent edition (ESRA3) data was collected simultaneously in 39 countries in 2023. In total, this third edition collected data from more than 37000 road users in 39 countries across five continents (Meesmann & Wardenier, 2024).

Vias institute in Brussels (Belgium) initiated and coordinates ESRA, in cooperation with ten steering group partners: BAST (Germany), DTU (Denmark), IATSS (Japan), ITS (Poland), KFV (Austria), NTUA (Greece), PRP (Portugal), SWOV (the Netherlands), TIRF (Canada), and University Gustave Eiffel (France).

For each country that participates in ESRA, there is a national partner to support the initiative. The national partner is responsible for the funding of the survey, the translation of the survey questionnaire into the national language(s) and interpretation of the findings. Funding for ESRA3 data collection in six Latin American countries was provided by Mapfre Foundation and for six additional European/Asian countries by WHO Regional office for Europe. A list of all partners (organisations and contact persons) supporting the ESRA3 survey can be found on page 3 of this report.

For ESRA3 the overall aim was to stay as close as possible to the ESRA2 study design. This includes method of data collection, formulation of items, sampling procedure, data processing and data cleaning. Some small adaptations were done in order to improve the study design, but efforts were made to maintain a high level of comparability with ESRA2.

2.3 Main ESRA3 outputs

All data collected in the different countries are centralised in the ESRA database. Teams of researchers explore this database and produce analyses, reports, articles, and indicators on road safety. One of the key characteristics of the ESRA dataset is the high comparability of data across countries. Moreover, with future editions in sight, ESRA is also a great source for analysing the development of road safety performance and culture over time.

The key results of the ESRA3 survey were published through a series of reports including this main report, a methodology report, 13 thematic reports (see Table 1), the ESRA3 dashboard and 39 country fact sheets. Already several of the country fact sheets have been translated to the national languages. In the country fact sheets national key results are compared to a regional mean (benchmark) and in the ESRA3 dashboard all national means of key results can be compared with other countries or regions.

Table 1: ESRA3 thematic reports

Driving under influence of alcohol, drugs and medication	Support for policy measures and enforcement	Pedestrians	Young and aging road users
Speeding	Subjective safety and risk perception	Cyclists	Male and female road users
Distraction (mobile phone use) and fatigue	Infrastructure	Riders of e-scooters	
Seatbelt & child restraint systems		Moped riders and motorcyclists	

Moreover, the ESRA3 results will be published again in a special issue in IATSS Research (Meesmann & Nakamura, 2025, in preparation) and were or will be presented at several conferences in 2024 and 2025. The final ESRA3 Conference will take place in June 2025 combined with an event celebrating 10 years of ESRA (23-24/06/2025). At this occasion the ESRA consortium will publish a '10-years ESRA report' with focus on evolution (Meesmann et al., 2025, in preparation). Furthermore, many ESRA partners use the ESRA3 dataset for their national road safety policy making, write national reports, use the data in other projects, contribute to conferences and write scientific articles. All common ESRA3 output has been peer-reviewed within the consortium, following a pre-defined quality control procedure. Results and news on the ESRA initiative can be freely consulted and downloaded at the ESRA website (www.esranet.eu). The website also offers the opportunity to sign up for the ESRA newsletter to keep informed about updates. For more information on quality control procedure see the detailed methodology report (Meesmann & Wardenier, 2024).

2.4 Costs and resources

From the beginning the intention was to keep costs as low as possible. The main principles to achieve this are: (1) using online panel services; and (2) sharing the analysis work amongst the ESRA partner organisations.

In most countries, the total cost for conducting the national survey with a sample of 1000 respondents was below €15000³. The costs differed between countries and were mainly determined by the local cost for conducting the survey and the sample size. The financial resources for the national survey costs and the staff time needed for the analyses were secured by the ESRA3 partners' own sources or regional sponsors.

The ESRA3 questionnaire was developed by Vias institute in collaboration with the ESRA3 steering group partners. National partners were responsible for the translations of the master version into their national language version(s). Furthermore, they were responsible for the validation of the national results and provided the contextual information necessary for the interpretation of the results. The analyses of the common data were a joint effort of the ESRA3 steering group members and Vias institute, who spend over 85 person months on analysing and producing the common ESRA3 outputs.

³ Total cost including national survey cost and contribution to ESRA3 project management and administration.

3 Methodology

3.1 Scope of the questionnaire

The ESRA3 questionnaire was largely based on the ESRA2 and ESRA1 questionnaires. Efforts were done to keep formulation of common questions and items with ESRA2 the same or highly comparable. Table 2 gives an overview of targeted road user groups, main themes, and road safety topics of the ESRA3 questionnaire. Overall, over 400 variables are included in the survey.

Table 2: ESRA3 survey targeted road users, road safety topics and themes.

Road users	Themes	Road safety topics
- car occupants - moped riders and motorcyclists - cyclists - pedestrians - e-scooter riders	- mobility and exposure - self-declared safe and unsafe behaviour in traffic - acceptability of safe and unsafe traffic behaviour - attitudes towards safe and unsafe traffic behaviour - subjective safety and risk perception - support for policy measures - enforcement - infrastructure (new) - road crash involvement - regional questions (new) - socio-demographic information	- speeding - driving under the influence of alcohol, drugs, and medication - protective systems (e.g., seat belt use, helmet use) - distraction - fatigue

The ESRA questions were derived from other road safety surveys that have been conducted in the past. Most of the questions were based on validated questionnaires from Belgium (Vias institute (former: BIVV/IBSR), the Three-yearly Road Safety Attitude Survey (Meesmann et al., 2014)), other European countries (SARTRE – Social Attitudes to Road Traffic Risk in Europe (Cestac & Delhomme, 2012), and the US (Traffic Safety Culture Index (AAA Foundation for Traffic Safety, 2016)). The questions reflect common topics related to road user behaviour, referred by the WHO as priorities in road safety (World Health Organization, 2023) and by the European Commission as suggested road safety performance indicators (European Commission, 2019).

Furthermore, for the interpretation of the results additional contextual information on country level was gathered via external data sources (e.g., CARE, Eurostat, IRF, OECD, WHO, World bank).

The median length of the interview was 23 minutes. The questionnaire was first developed in English by the ESRA3 steering group, based on the experience with ESRA2 and ESRA1 and subsequently translated into 49 national language versions by the ESRA3 partners. The survey was programmed in seven different character sets: Armenian alphabet, Cyrillic, Greek, Hebrew, Japanese, Latin and Thai.

3.2 Online panel survey

ESRA data is derived from an extensive online survey amongst a representative sample of the national adult populations in each participating country. More specifically, ESRA3 is based on a web-based survey using internet panels.

This approach has some advantages compared to other survey modes, especially given the international context of the study. These advantages are:

- Self-administered web surveys are less prone to social desirability in responses compared to interviewer-administered surveys (Baker et al., 2010; De Leeuw et al., 2008; Goldenbeld & De Craen, 2013).
- The common study design provides better comparability across countries (i.e., identical criteria in sampling procedure, identical programming of questionnaire; one project management across all countries as the ESRA survey is actually 'one' survey which is linked to different national translations).

- Reduction of time (fieldwork in most countries ca. 2-3 weeks; efficient data processing), workload (e.g., less time for fieldwork and data processing) and costs (national survey costs in most countries was below €15000⁴).

In Armenia, Kyrgyzstan and Uzbekistan it was not possible to conduct an online panel survey. Therefore, the respondents in these countries were recruited on the street of different major cities spread over the country (face to face recruitment) and invited to participate in a computer assisted personal interview (CAPI). For more information on these exceptions and limitations of online surveys see section 4.9 'Limitations and points of attention for the future'.

3.3 Sampling and fieldwork

The survey targets all main types of road users. The aim is to cover a representative sample of the national adult population of at least 1000 respondents in each country. Hard quotas are used for gender and age (six age groups: 18-24y, 25-34y, 35-44y, 45-54y, 55-64y, 65-74y) distribution during the sampling procedure (United Nations Statistics Division, 2023). In the three countries Armenia, Kyrgyzstan and Uzbekistan, data collection was limited to the three youngest age categories as no hard quota could be guaranteed for the older age groups and because the sample design was limited to 500 respondents. The geographical spread of the sample across the country was at least monitored (soft quota). Three market research agencies (Dynata, Ipsos and Punto de Fuga) organised the fieldwork under the supervision of Vias institute. The fieldwork was conducted simultaneously in all 39 participating countries between May and September 2023.

3.4 Data processing and quality control

In order to maximise cross-national comparability of data, the programming of the survey, the data collection in all countries, and the data processing were centrally organized by Vias institute and the ESRA steering group. The statistical software used in the data processing, analyses and output of the data were SPSS 29.0 (IBM Corp., 2022) and R 4.3.1 (R Core Team, 2023).

Data preparation

The selected market research agencies for ESRA3 data collection had to respect minimum criteria for data cleaning (pre-cleaning) and a custom-made database template, which were provided by Vias institute. Vias institute merged the pre-cleaned datasets from all 39 countries into one single database and conducted further quality checks.

Before further data cleaning, Vias institute performed the following quality controls:

1. checked data against pre-defined ESRA3 codebook;
2. merged datasets from the three agencies;
3. verified programming consistency (e.g., filters vs. expected missing values);
4. ensured adherence to national sample quotas for gender and age ($\pm 5\%$ deviation allowed).

Minor issues in steps 1-3 were corrected without affecting data quality. Step 4 deviations were adjusted using small weighting factors based on population distributions (United Nations Statistics Division, 2023).

Data cleaning

The data files provided by the market research companies had to respect a specific template. All the national data files were merged into one file, including the answers of all respondents in 39 countries. Vias institute checked the quality of the data and carried out a second data cleaning, which included controlling for duplicate entries, removing inconsistencies with panel information, checking for the length of the interview (identifying and eliminating 'speeders' and 'turtles'), removing straightliners (respondents who give the same answers for many questions), and removing careless respondents who answered wrong on at least one of the two instructed response items (trick items: e.g., "indicate number

⁴ National survey cost including contribution to ESRA3 project management and administration.

5 on the answer scale”). From the original, pre-cleaned dataset provided by the market research agencies (N=42835), 5742 (13.4%) respondents were removed. The final sample consists out of n=37093 respondents.

Data processing

In view of facilitating analysis and dissemination of ESRA3 results, for some questions the original answer categories (mainly 5-point and 7-point scales) were dichotomized (i.e., grouping answers into two groups and creating a binary variable). The dichotomization process was conducted centrally by Vias institute and used in presenting all descriptive analyses of the ESRA3 reports. The dichotomizations and reference categories for each question are indicated in the ESRA3 questionnaire in Appendix 1 (see information on binary variable).

A weighting of the data was applied in the descriptive analyses. This weighting was meant to correct for small deviations in the sample of representative gender and age groups for the countries: 18-24y, 25-34y, 35-44y, 45-54y, 55-64y, 65-74y (United Nations Statistics Division, 2023). For the regional means, the weighting also took into account the relative size of the population of each country within the total set of countries from this region (for more details on weighting see Appendix 2).

Data quality control

PRP (Portugal) in collaboration with Vias institute (Belgium) was responsible for the quality control of the standardized data cleaning and data processing procedure, and for the extraction of standardized figures which were used in all common ESRA3 outputs. The national partners were asked to validate the national datafiles and the country fact sheets before common output was published.

A full overview of the data cleaning and data processing can be found in the ESRA3 methodology report (Meesmann & Wardenier, 2024).

3.5 Sample characteristics

Geographical coverage

The ESRA3 data is based on the answers to the survey questions from more than 37000 road users across 39 countries. The participating countries in ESRA3 were:

- Europe22: Austria, Belgium, Bosnia and Herzegovina, Czech Republic, Denmark, Finland, France, Germany, Greece, Ireland, Italy, Latvia, Luxembourg, Netherlands, Poland, Portugal, Republic of Serbia, Slovenia, Spain, Sweden, Switzerland, United Kingdom;
- America8: Brazil, Canada, Chile, Colombia, Mexico, Panama, Peru, USA;
- AsiaOceania6: Australia, Israel, Japan, Kazakhstan, Thailand, Türkiye, (Armenia, Kyrgyzstan and Uzbekistan).

Due to different methodology in data collection Armenia, Kyrgyzstan and Uzbekistan are not included in the AsiaOceania6 regional group (face-to-face CAPI instead of online panel).

Figure 2 shows the geographical coverage of the survey. Details on the fieldwork per country can be found in Table 4 in Appendix 3.

Figure 2: Geographical coverage of the ESRA3 survey.

Regional differences

Table 3 shows the sample size, national internet penetration and the distribution of gender and age by geographical region. The gender distribution is very similar between the three regions: on regional level the proportion of men varies between 49% and 49.5%, the proportion of women varies between 50.2% and 50.8% and the proportion of other varies between 0.2% and 0.5%.

Table 3: Sample size, internet use, gender and age distribution by region (weighed means).

Region	Sample size	Internet-users in 2021 or 2022 (per 100 people)	Gender			Age group					
			male	female	other	18-24y	25-34y	35-44y	45-54y	55-64y	65y+
Europe22	22000	79 - 98	49.5%	50.3%	0.2%	10.8%	17.1%	18.5%	19.7%	18.8%	15.1%
America8	8000	68 - 93	49.0%	50.8%	0.2%	15.3%	21.9%	19.5%	17.2%	15.3%	10.7%
AsiaOceania6*	6000	77 - 96	49.4%	50.2%	0.5%	12.9%	19.8%	20.0%	19.5%	14.9%	13.0%

Note. (1) Reference population: all road users. (2) Regional weighed means for gender and age group. (3) Source internet use per country (data from 2021 or 2022): The World Bank Group (2024). (4) * Armenia, Kyrgyzstan, Uzbekistan not included due to different methodology (face-to-face CAPI).

Figure 3 shows the age distribution by region. The sample has been weighted according to gender and age distribution of population statistics (United Nations Statistics Division, 2023). Therefore, it represents the demographic characteristics of the regional samples (e.g., older population in the European region compared to the other regions). The ESRA3 sample was limited to respondents between 18 and 74 years old, except for Armenia, Kyrgyzstan and Uzbekistan where the age limit was reduced to 18-44 years olds (different methodology and smaller sample size; see also section 3.2 'Online panel survey', section 3.3 'Sampling and fieldwork' and section 4.9 'Limitations and points of attention for the future'). Therefore, Armenia, Kyrgyzstan and Uzbekistan are not included in the Asian-Oceanian regional means which are presented in ESRA3 output. In European countries the average age is 46.1 years with a standard deviation of 15.4 and a median age of 46 years. The average age in American countries is 42.4 years with a standard deviation of 15.3, 40 years is the median age. Lastly, in the Asian-Oceanian countries (excluding Armenia, Kyrgyzstan and Uzbekistan) the average age of respondents is 43.8 with a standard deviation of 15.3. The median age in this region is 43.

* Armenia, Kyrgyzstan, Uzbekistan not included due to different methodology (face-to-face CAPI).

Figure 3: Age distribution by region (weighted means).

It should also be noted that the unweighted share of the oldest age group 65-74y (see Appendix 6) varies strongly by country. This is to some extent the result of their real share in the population (United Nations Statistics Division, 2023), but in some cases, it is also due to underrepresentation of this age group within the unweighted sample (Brazil, Colombia, Peru, Thailand, Bosnia and Herzegovina, Kazakhstan, Türkiye, and Panama).

The internet penetration in a country can serve as an indication for the representativeness of an online panel sample for the national population. As Table 3 and Table 5 in Appendix 6 show, the number of internet-users⁵ is in most participating countries very high, it ranges between 68% and 98% with an average of 87%. It is above 75% in all countries, except for Panama (68%) and Colombia (73%).

The means for results at regional level are based on weighted data. Details on the unweighted national samples can be found in Appendix 6 and (Meesmann & Wardenier, 2024).

⁵ Includes people younger than 18y and above 74y. Internet penetration is shown for the most recent year available. For most countries this is 2022, if not it is 2021.

4 Key results from the ESRA3 survey

This report focusses on the presentation of regional results and the comparison across the main road safety topics of the ESRA3 survey. Those were i.e.: speeding, driving under the influence of alcohol, drugs and medication, protective systems (e.g., seat belt use, helmet use), distraction (mobile phone use), and fatigue. All national results can be found in Appendix 7 and in the according thematic reports.

4.1 Use of transport modes

Respondents were asked how often they used one or more transport modes in the last 12 months. Multiple answers were possible. Figure 4 presents the percentage of respondents who stated that they used a certain mode of transport at least a few days a month (in ESRA defined as 'frequent use of transport modes'). The results are presented per region (for national results and more statistical information see Table 6 in Appendix 7).

Figure 4: Use of transport modes, by region.

Walking ("walking or running minimum 200m down the street"), traveling by car as a driver or as a passenger, and using public transport are the most frequent modes of transport in the three regions. More than 60% of the respondents reported using these transport modes at least a few days a month. Cycling⁶ (at least a few days a month) was reported by almost half of European (48.4%) and American (49.6%) respondents and by 42.1% in AsiaOceania6. Riding a motorcycle or moped is more common in America8 (33.1%) and in AsiaOceania6 (28.5%) than in Europe22 (17.0%). Riding an e-scooter was the least frequent transport mode used by respondents in the three regions. In America8, 21.0% of the respondents reported riding an e-scooter (at least a few days a month), in AsiaOceania6 and in Europe22 this was 13.3%.

In general, the use of almost all transport modes is more frequently reported by men than by women. However, these differences are small for being a pedestrian and for using public transport. Being a passenger in a car is more frequently reported by women than men in Europe22 and in AsiaOceania6.

Overall, the data show that in all the regions older road users report less the use of all the transport modes than the younger ones. The age group differences are stronger for cycling, riding a moped or a motorcycle, and riding an e-scooter. Driving a car is an exception – it is less declared by younger respondents (18-24y) compared to older respondents.

⁶ Including non-electric and electric cycling (see also Appendix 4)

4.2 Self-declared unsafe behaviour in traffic

In order to assess the prevalence of different types of unsafe behaviour in traffic, respondents needed to indicate whether they had engaged in a certain behaviour over the last 30 days. The types of unsafe traffic behaviour included speeding, distraction, (not using) protective systems, driving under influence, and fatigue. In the following section the regional results are presented per road user group. Note, that many respondents belong to more than one road user group.

4.2.1 Car drivers and car passengers

Figure 5 shows the self-declared unsafe behaviour of car drivers and car passengers for each of the three regions. The national results and more statistical information can be found in Table 7 to Table 10 in Appendix 7. The figure presents the percentage of car drivers and car passengers who stated that they had engaged in a certain behaviour at least once over the last 30 days.

Overall, speeding and talking on a hands-free mobile phone while driving a car are the most frequently reported behaviours by car drivers in the three regions. Self-declared traveling without the seatbelt in the backseat as a passenger is also high, especially in America8 and AsiaOceania6.

Around half of European car drivers declared driving faster than the speed limit inside built-up areas (47.3%), on motorways/freeways (49.7%) and outside built-up areas (except motorways/freeways) (52.8%). These percentages were higher than the ones observed in America8 (39.6%, 46.0%, and 42.5%, respectively) and in AsiaOceania6 (37.1%, 39.1%, and 41.6%, respectively). Car drivers seem to be more careful with speeding in difficult traffic conditions: the percentages of car drivers who declared driving too fast for the road/traffic conditions at the time (e.g., poor visibility, dense traffic, presence of vulnerable road users) was lower in all three regions: 30.5% in Europe22, 27.8% in America8, and 31.0% in AsiaOceania6.

Talking on a hands-free mobile phone while driving a car was reported by 51.0% of the car drivers in Europe22, 47.6% in America8, and 44.3% in AsiaOceania6. It was the most frequently declared behaviour by car drivers in the last two regions. These percentages were higher than the ones of handling a mobile phone while driving a car: talking on a hand-held mobile phone and reading a message or checking social media/news were declared by respectively 22.2% and 23.2% of the respondents in Europe22, by 30.5% and 31.5% in America8, and by 27.6% and 24.5% in AsiaOceania6.

Interestingly, the non-use of seatbelts and child restraint systems is much lower in Europe22 than in America8 and in AsiaOceania6, with similar percentages in these two regions. As car passengers, 32.0% of European passengers declared traveling without a seatbelt in the back seat (51.7% in America8 and 53.1% in AsiaOceania6) and 14.7% in the front seat (26.4% in America8 and 23.4% in AsiaOceania6). The percentages of car drivers who declared driving without seatbelt (15.0%) and transporting children without using child restraint systems (15.6%-18.3%) are also lower in Europe22 than the correspondent percentages in America8 (23.4%, 23.7%-31.6%, respectively) and in AsiaOceania6 (20.9%, 28.0%-33.2%, respectively).

Fatigued driving at least once in the past 30 days was reported by about one out of five car drivers in all the regions: 18.4% in the Europe22 region, 18.6% in America8 region, and 20.1% in AsiaOceania6 region.

Reference population: car drivers/passengers at least a few days a month, *not including Armenia, Kyrgyzstan, Uzbekistan (different methodology), **specified based on national regulation

Figure 5: Self-declared behaviour as a car driver & car passenger, by region.

Overall, driving under the influence of alcohol or drugs was amongst the least frequently declared unsafe behaviour in all regions. Driving after drinking alcohol was declared by 15.4% of car drivers in Europe22, 17.4% in America8, and 11.3% in AsiaOceania6. Driving over the legal limit for drinking and driving was declared by 11.6% of car drivers in Europe22, 14.0% in America8, and 10.0% in AsiaOceania6. In Europe22 13.4% of the car drivers reported driving within 2 hours after taking medication that may affect the driving ability, in America8 this was 16.1% and in AsiaOceania6 14.5%. Driving within 1 hour after taking drugs (other than prescribed or over the counter medication) was declared by 7.2% of car drivers in Europe22, 13.3% in America8, and 11.8% in AsiaOceania6.

Overall, male car drivers and passengers reported more unsafe behaviour in traffic than female ones. Younger car drivers (18-24y and 25-34y) tend to report more unsafe behaviour in traffic than the older drivers (45-54y, 55-64y and 65-74). However, for some self-declared behaviours, in some regions the age group differences are small and there is hardly an age gradient.

4.2.2 Moped riders and motorcyclists

The ESRA3 questionnaire included six questions related to self-declared unsafe traffic behaviour of motorcyclists and moped riders. The results per region are presented in Figure 6 (for national results and more statistical information see Table 11 in Appendix 7). The figure shows the percentage of moped riders and motorcyclists who stated that they had engaged in a certain behaviour at least once over the last 30 days.

The prevalence of the self-declared behaviours was not very different among the three regions, except for riding without a helmet, whose percentage was much higher in AsiaOceania6 (37.7%) than in Europe22 (24.5%) and in America8 (26.2%). Riding faster than the speed limit outside built-up areas was declared by 30.1%-35.1% of the riders and riding too fast for the road/traffic conditions at the time by 26.6%-30.4%. 20.7% to 24.9% of the riders reported reading a message or checking social media/news while riding. Riding when you may have been over the legal limit for drinking and driving was declared by 17.7%-19.4% and riding within 1 hour after taking drugs (other than prescribed or over the counter medication) by 17.1%-22.7%.

Figure 6: Self-declared behaviour as a motorcyclist and moped rider, by region.

In general, male moped riders or motorcyclists engage more in unsafe behaviour than female riders except in Europe22 where there is no clear gender effect. Furthermore, as for car drivers, younger European moped riders and motorcyclists tend to ride less safe than older age categories. These results are not observed in the other regions.

4.2.3 Cyclists

The ESRA3 questionnaire included six questions related to self-declared unsafe behaviour of cyclists. The results per region are presented in Figure 7. Details on the national results and more statistical information can be found in Table 12 in Appendix 7. The figure shows the percentage of cyclists who stated that they engaged in a certain behaviour at least once over the last 30 days.

More than half of the cyclists in Europe22 (60.4%) and AsiaOceania6 (56.5%) declared cycling without a helmet – it was the most frequently declared behaviour in both regions. In America8, 42.9% reported cycling without a helmet. In this region, cycling while listening to music through headphones was the most common behaviour – declared by 51.4% of the cyclists – a percentage much higher than the ones observed in Europe22 (35.5%) and AsiaOceania6 (36.4%).

In all the regions between 19.5% to 24.0% declared reading a message or checking social media while cycling and 24.7% to 30.5% crossing when a traffic light is red at least once in the last 30 days.

Cycling under the influence of drugs ("cycle within 1 hour after taking drugs (other than prescribed or over the counter medication)") or alcohol ("cycle when you think you may have had too much to drink") was the least declared unsafe behaviour in the three regions: 9.1% and 16.4% in Europe22 respectively; 12.8% and 14.3% in America8 respectively; 13.3% and 12.8% in AsiaOceania6 respectively.

Male cyclists tend to declare risky behaviour more frequently than female cyclists, mainly cycling under the influence of alcohol and drugs, but cyclists from older age categories report in general less unsafe behaviour than younger cyclists.

Figure 7: Self-declared behaviour as a cyclist, by region.

4.2.4 Pedestrians

The ESRA3 questionnaire included six questions related to self-declared unsafe behaviour of pedestrians in traffic. The results per region are presented in Figure 8 (for national results and more statistical information see Table 13 in Appendix 7). The figure shows the percentage of pedestrians who stated that they had engaged in a certain behaviour at least once over the last 30 days.

In all regions the most frequently reported unsafe behaviour of pedestrians is crossing the street without using a nearby pedestrian crossing. In Europe22, 66.8% of the pedestrians reported this behaviour, 59.3% in America8, and 54.6% in AsiaOceania6. A smaller percentage declared crossing the road when a pedestrian light is red: 44.6% in Europe22, 41.3% in America8, and 35.7% in AsiaOceania6.

More than half of the pedestrians in the three regions declared reading a message/checking social media (63.7% in Europe22, 58.4% in America8, and 53.3% in AsiaOceania6) or text a message while walking down the street (60.3% in Europe22, 57.0% in America8, and 51.6% in AsiaOceania6). Listening to music through headphones was also declared by more than half of the American pedestrians (55.0%), but by a smaller percentage in Europe22 (44.2%) and in AsiaOceania6 (43.4%).

Between 25.9% on pedestrians in AsiaOceania6 and 31.8% of European pedestrians declared walking down the street when they think they may have had too much to drink.

In all regions gender differences are rather small for most self-declared unsafe traffic behaviours, except for walking when they think they may have had too much to drink – the percentages are much higher for male than for female pedestrians. Additionally, as for the other transport modes, pedestrians from younger age categories report in general a higher frequency of unsafe behaviour than older pedestrians.

Figure 8: Self-declared behaviour as a pedestrian, by region.

4.2.5 E-scooter riders

The ESRA3 questionnaire included five questions related to self-declared unsafe behaviour of e-scooter riders. The results per region are presented in Figure 9 (for national results and more statistical information see Table 14 in Appendix 7). The figure shows the percentage of pedestrians who stated that they had engaged in a certain behaviour at least once over the last 30 days.

Riding an e-scooter without a helmet (44.6%) and riding on the pedestrian pavement/sidewalk (44.4%) were the most frequently declared behaviours by the European e-scooter riders. Both behaviours were also the most declared in AsiaOceania6 (by 39.6% and 38.2% respectively) together with riding with more than 1 person on board (38.1%). These behaviours were all less declared in America6: 26.0% declared riding an e-scooter without a helmet, 33.2% riding on pedestrian pavement/sidewalk, and 30.7% riding with more than 1 person on board. Between 21.2% of e-scooter riders in America8 and 28.5% in AsiaOceania6 declared crossing the road when the traffic light is red. Riding an e-scooter when they think they may have had too much to drink was reported by between 16.9% in America8 and 20.9% in AsiaOceania6. Only small differences in the unsafe behaviour prevalence were found regarding gender or age.

Figure 9: Self-declared behaviour as a e-scooter rider, by region.

4.3 Acceptability of unsafe behaviour in traffic

In line with previous editions, the ESRA survey asked all road users whether they personally consider certain car-driving behaviours acceptable. In ESRA3, this question was expanded to include unsafe traffic behaviours of other road users. The corresponding results are presented in the following sections.

4.3.1 Car drivers

Two questions in the ESRA3 survey were meant to collect data on the acceptability of unsafe behaviour in traffic. One question was about the personal acceptability⁷ of unsafe behaviour as a car driver and the other one about the perceived social acceptability⁸ (social norm) related to this behaviour. Figure 10 presents the results of per region (for national results and more statistical information see Table 15 and Table 16 in Appendix 7).

Of all the behaviours listed, talking on a hands-free mobile phone while driving a car is the most acceptable across the regions, with higher acceptability in Europe22 (38.6%) than in America8 (23.9%) and AsiaOceania6 (28.5%). This behaviour is considered much more acceptable than talking on a hand-held mobile phone or reading a message or checking social media/news in the three regions – less than 5% of respondents considered these behaviours acceptable.

A clear decreasing trend of personal acceptability of speeding according to the road type/traffic conditions was observed in the three regions: speeding on motorways/freeways is the most acceptable behaviour, with an acceptability rate between 9.7% and 13.2%, followed by speeding outside built-up areas (7.7%-9.5%), speeding inside built-up areas (4.7%-4.9%), and driving too fast for road or traffic conditions, such as poor visibility or dense traffic (2.9%-4.3%).

Less than 5% of the respondents considered driving without wearing the seatbelt acceptable in the three regions (4.6%-4.9%). There is also a low acceptability for transporting children in the car without securing them (child's car seat, seatbelt, etc.), while it is still higher in America8 (4.7%) and AsiaOceania6 (5.3%) than in Europe22 (2.8%).

The acceptability of driving under influence (DUI) is also quite low, with small differences among the regions: DUI of alcohol was considered acceptable by 2.6%-3.7% of respondents, driving within 1 hour after taking drugs by 2.6%-4.0%, and driving within 2 hours after taking a medication that may affect the driving ability by 3.8%-5.3%.

Fatigued driving (driving a car while having trouble keeping the eyes open) is among the least acceptable behaviours in the three regions, with percentages of acceptability similar to DUI of alcohol: 2.5% in Europe22, 3.5% in America8, and 2.7% in AsiaOceania6.

⁷ "How acceptable do you, personally, feel it is for a car driver to...?"

⁸ "Where you live, how acceptable would most other people say it is for a car driver to...?"

Figure 10: Personal acceptability of car driver's unsafe traffic behaviours, by region.

Figure 11 presents the results of perceived social acceptability (social norm) of unsafe behaviour as a car driver per region (for national results and more statistical information see Table 17 in Appendix 7). The results of the correspondent behaviours of personal acceptability are also included in the figure.

The results show that the percentages of the perceived social acceptability are higher than the ones of personal acceptability for the same behaviours, meaning that the respondents think that "others" consider the unsafe behaviours in traffic to be more acceptable than they do themselves. This pattern is observed in all the regions for all the behaviours analysed.

Both social and personal acceptability of unsafe behaviour are in general higher among men than among women, except in AsiaOceania6, where differences between men and women do not show a consistent pattern. In most regions younger age categories systematically report higher social acceptability and personal acceptability of unsafe traffic behaviour than older age categories.

Acceptability of unsafe behaviour in traffic

Reference population: all road users, *not including Armenia, Kyrgyzstan, Uzbekistan (different methodology)

Figure 11: Personal and social acceptability of car driver's unsafe traffic behaviours, by region.

4.3.2 Moped riders and motorcyclists

The ESRA3 questionnaire included four items related to personal acceptability of moped riders and motorcyclist's unsafe traffic behaviours. Figure 12 presents the results per region (for national results and more statistical information see Table 18 in Appendix 7).

Riding a moped or motorcycle faster than the speed limit outside built-up areas (excluding motorways/freeways) is the most accepted behaviour, with percentages of acceptability of 7.5% in Europe22, 5.7% in America8, and 6.5% in AsiaOceania6. On the contrary, reading a message or checking social media/news while riding and riding over the legal limit for alcohol were the least accepted behaviours in the three regions – these behaviours were considered acceptable by 4% of the respondents or less. The percentage of acceptability for not wearing a helmet on a moped or motorcycle ranged from 3.9% in Europe22 to 5.3% in America8 and AsiaOceania6.

Men in Europe22 and in America8 considered the unsafe behaviours more acceptable than women, but no differences exist in AsiaOceania6. In Europe22 and AsiaOceania6, younger respondents consider most of the behaviours more acceptable than older ones, while no consistent age-related pattern is observed in America8.

Figure 12: Personal acceptability of moped riders and motorcyclist's unsafe traffic behaviours, by region.

4.3.3 Cyclists

The ESRA3 questionnaire also included four items related to personal acceptability of cyclist's unsafe traffic behaviours. Figure 13 presents the results per region (for national results and more statistical information see Table 19 in Appendix 7).

Cycling without a helmet is the most accepted behaviour across the three regions, with higher acceptability in Europe22 (20.9%) and AsiaOceania6 (17.5%) than in America8 (10.9%). Crossing the road when a traffic light is red is considered less acceptable in Europe22 (3.6%) than in America8 (7.9%) and AsiaOceania6 (9.5%). Cycling when the cyclist may have had too much to drink and reading a message or checking social media/news while cycling is considered acceptable by less than 5% of the respondents.

The cyclist's unsafe behaviours are considered more acceptable by men than by women in Europe22 and in America8, but no gender differences exist in AsiaOceania6. Younger respondents consider the unsafe behaviours more acceptable than the older ones in the three regions.

Figure 13: Personal acceptability of cyclist's unsafe traffic behaviours, by region.

4.3.4 Pedestrians

Three items to assess the personal acceptability of pedestrian's unsafe traffic behaviours were included in the ESRA3 survey. Figure 14 presents the results per region (for national results and more statistical information see Table 20 in Appendix 7).

Crossing the road when a pedestrian light is red is the least accepted behaviour in the three regions, with similar percentages of acceptability (8.5%-8.9%). Walking down the street when the pedestrian

may have had too much to drink and reading a message or checking social media/news while walking down the street is considered more acceptable in Europe22 (25.5% and 31.2% respectively) than in America8 (12.9% and 18.8% respectively) and AsiaOceania6 (15.5% and 16.7% respectively).

As for the acceptability of other road user's behaviours, the pedestrians' unsafe behaviours are more accepted by men than by women in Europe22⁹ and in America8, but small or no gender differences exist in AsiaOceania6¹⁰. Younger respondents consider the unsafe behaviours more acceptable than the older ones in the three regions, except for walking down the street when the pedestrian may have had too much to drink in AsiaOceania6 where the percentages are similar across the age groups.

Figure 14: Personal acceptability of pedestrian's unsafe traffic behaviours, by region.

4.4 Attitudes and perceived behaviour control

The ESRA3 survey included several questions related to the psychological concepts 'attitudes' and 'perceived behaviour control'. The respondents were asked to indicate on a 5-point scale, where 1 is "disagree" and 5 is "agree", to what extent they agree with each of the following statements:

Attitudes:

- For short trips, one can risk driving under the influence of alcohol.
- I have to drive fast; otherwise, I have the impression of losing time.
- Respecting speed limits is boring or dull.
- I use a mobile phone while driving, because I always want to be available.
- To save time, I often use a mobile phone while driving.

Perceived behaviour control:

- I trust myself to drive after drinking a small amount of alcohol (e.g., one glass of wine or one pint of beer).
- I have the ability to drive when I am a little drunk after a party.
- I am able to drive after drinking a large amount of alcohol (e.g., a bottle of wine).
- I trust myself when I drive significantly faster than the speed limit.
- I have the ability to drive significantly faster than the speed limit.
- I am able to drive fast through a sharp curve.
- I trust myself when I check messages on the mobile phone while driving.
- I have the ability to write a message on the mobile phone while driving.
- I am able to talk on a hand-held mobile phone while driving.

⁹ Only exception: No significant gender differences was identified for the acceptability of reading a message or check social/media while walking down the street in Europe.

¹⁰ Only significant gender difference in Asia-Oceania6: Walk down the street when he/she may have had too much to drink is more acceptable among male respondents compared to female respondents.

The according questions and answers can be found in Appendix 1 (Q17). Composite scores for these concepts were created based on an explorative factor analysis¹¹. For 'attitudes' this is a composite score of items across all road safety topics (speeding, driving under the influence of alcohol, and mobile phone use). For 'perceived behaviour control' (PBC) composite scores were made per road safety topic. In both cases, the higher the mean score, the higher the percentage of respondents with risky road safety beliefs. Figure 15 presents the results per region (for national results and more statistical information see Table 21 in Appendix 7).

Figure 15: Composite mean scores for Attitudes and Perceived Behaviour Control: DUI (alcohol), distraction (mobile phone), and speeding, by region (high score → more risky opinion).

Figure 15 shows similar risky road safety attitudes across the regions with a mean score of 1.47 in Europe22 and America8 and 1.51 in AsiaOceania6. The results with respect to perceived behaviour control show different patterns across the regions: while in Europe22 and America8 the perceived ability to control the car while speeding has the highest mean, in AsiaOceania6 this mean is similar to the PBC for using a mobile phone. The perceptions of being able to DUI of alcohol and while speeding are the highest in Europe22 and the lowest in AsiaOceania6.

In all regions, men have more risky road safety attitudes compared to women. The same is true for the perceived behaviour control. Men more often perceive that they can control the car after drinking alcohol, while speeding or using a mobile phone. Overall, in all the regions, younger age categories systematically report higher risky attitudes and higher perception that they can control the car under the influence of alcohol, while speeding or using the mobile phone than older age categories. The only exceptions are for the perceived behaviour control of DUI alcohol in America8 where there are no age differences.

4.5 Subjective safety and risk perception

Respondents were asked how safe they felt while using different transport modes (if they had not used a certain transport mode in the last 12 months, they did not get this question). They could indicate their answer on a scale from 0-10 where 0 was 'very unsafe' and 10 'very safe'. Figure 16 shows the mean scores by region. The results for each country and more statistical information can be found in Table 22 in Appendix 7.

Riding an e-scooter, riding a moped or motorcycle, and cycling were considered the least safe transport modes in the three regions. Different patterns were observed in relation to the safest transport modes: while in Europe22 and in AsiaOceania6 walking as a pedestrian and using public transport are considered the safest transport modes, in America8 traveling by car, either as a driver or passenger, are considered the safest options.

¹¹ The explorative factor analysis showed that all questions related to the concept 'attitudes' including all road safety topics loaded on one dimension, which indicated that they could be combined. The questions related to the concept 'perceived behaviour control' had to be separated by road safety topic as they loaded on one dimension per road safety topic.

In all the regions women tend to feel less safe when using public transports and walking as a pedestrian than men, however the gender differences are small. The same trend is seen in Europe22 for driving a car, cycling, riding moped or motorcycle, and riding an e-scooter. No clear age pattern is observed for safety perceptions.

Figure 16: Subjective safety feeling, by region (high score → safer feeling).

The risk perception of the traffic behaviours was assessed by asking “How often do you think each of the following factors is the cause of a road crash involving a car?”. Figure 17 shows the percentage of drivers who thought that a certain behaviour is often or frequently the cause of an accident. The results are presented by region. The related national results and more statistical information can be found in Table 23 in Appendix 7.

The risk perception of the unsafe behaviours is the highest in Europe22, followed by America8, and the lowest in AsiaOceania6. This is observed in all the behaviours except for using a hands-free mobile phone while driving a car, where the risk perception is higher in America8 than in Europe22 – this also was considered the least risky behaviour in both regions. Excluding the use of a hands-free mobile phone while driving a car, the rates of the other unsafe behaviours were close in Europe22 (it ranged from 61.4% for driving within 1 hour after taking drugs (other than prescribed or over the counter medication) to 69.7% for driving after drinking alcohol) and in America8 (it ranged from 49.8% for driving within 1 hour after taking drugs (other than prescribed or over the counter medication) to 55.5% for driving after drinking alcohol). In AsiaOceania6 using a hands-free mobile phone while driving a car is also considered the least unsafe behaviour (31.2%), but with a rate closer to the other behaviours. Driving faster than the speed limit is considered the riskiest behaviour in this region (38.8%).

In Europe22 women considered the driving behaviours listed to be riskier than men, but no gender differences were found in America8 or in AsiaOceania6. The risk perception is higher in older drivers than in the younger ones in Europe22 and in America8, but do not differ across age groups in AsiaOceania6.

Figure 17: Risk perception - causes of road car crash, by region ('How often do you think each of the following factors is the cause of a road crash involving a car?').

4.6 Traffic law enforcement

To assess the perceived likelihood of being checked by the police, the ESRA3 survey included one question¹² with five items. Figure 18 presents the results per region for this question (for national results and more statistical information see Table 24 in Appendix 7). The figure shows the percentage of respondents who think that it is likely that they as a car driver on a typical journey, will be checked by the police for a certain unsafe traffic behaviour.

The perceived likelihood of being checked is the highest in AsiaOceania6, followed by America8, and the lowest in Europe22. This pattern is observed in all the behaviours except for the use of illegal drugs and the use of hand-held mobile phone to talk or text while driving for which there are no differences between Europe22 and America8.

In all regions, the reported likelihood of being checked is the highest for respecting the speed limits (Europe22: 36.4%, America8: 43.5%, AsiaOceania6: 52.3%) and for wearing the seatbelt (Europe22: 28.9%, America8: 45.3%, AsiaOceania6: 50.7%). Being checked by the police for the use of illegal drugs is perceived as the most unlikely in all regions (Europe22: 10.9%, America8: 12.4%, AsiaOceania6: 20.3%).

Male drivers tend to report a higher perceived likelihood of being checked for traffic violations than female drivers, with higher differences in Europe22 and America8 than in AsiaOceania6. Older drivers in general report a lower likelihood of being checked than younger ones in Europe22 and America8, no significant difference was observed for AsiaOceania6.

¹² "On a typical journey, how likely is it that you (as a car driver) will be checked by the police for..."

Reference population: car drivers at least a few days a year, *not including Armenia, Kyrgyzstan, Uzbekistan (different methodology)

Figure 18: Enforcement perception, by region ('On a typical journey, how likely is it that you (as a car driver) will be checked by the police for...').

The ESRA3 questionnaire also asked car drivers about their experience of being checked by the police for using alcohol and for using drugs while driving a car in the past 12 months. Figure 19 shows the results per region (for national results and more statistical information see Table 25 in Appendix 7).

In all regions, there are more reported checks by the police for driving under the influence of alcohol than for drugs. The percentages of reported alcohol checks are close to each other across the regions: 18.8% in Europe22, 20.7% in America8, and 17.5% in AsiaOceania6. Being checked by the police for using drugs (other than prescribed or over the counter medication) was more reported in America8 (8.2%) than in Europe22 (5.5%) and in AsiaOceania6 (5.8%).

Male drivers report more checks for using alcohol and drugs than female drivers and younger drivers had more experience with being checked for alcohol and drugs than older age categories. Both gender and age patterns are observed in all the regions.

Reference population: car drivers at least a few days a year, *not including Armenia, Kyrgyzstan, Uzbekistan (different methodology)

Figure 19: Police checks for using alcohol (i.e., being subjected to a Breathalyser test) and for the use of drugs (other than medication) while driving a car, by region.

4.7 Public support for policy measures

To assess public support for policy measures, respondents were asked whether they would support or oppose certain policy measures to be implemented¹³. Figure 20 presents the results per region for this question (for national results and more statistical information see Table 26 in Appendix 7). The figure

¹³ "Do you oppose or support a legal obligation to ...?"

shows the percentage of respondents supporting the idea that a particular measure would be a legal obligation.

In all regions, almost all policy measures listed are supported by the majority of the respondents. Only the measures related to speeding (the least supported measures) are not supported by more than 65% of the respondents in all regions: limiting the speed limit to 30 km/h in all built-up areas (except on main thoroughfares) is supported by 42.1% of respondents in Europe22, 54.8% in America8, and 46.5% AsiaOceania6; limiting the speed limit to a maximum of 80 km/h on all rural roads without a median strip is supported by 48.8% of respondents in Europe22, 64.6% in America8, and 53.0% AsiaOceania6. The support for both measures on speeding is the highest in America8, followed by AsiaOceania6, and the lowest in Europe22.

Overall, requiring cyclists under the age of 12 to wear helmets is the measure with the highest support, with 86.1% in America8, followed by 83.4% in Europe22 and 76.2% in AsiaOceania6. Requiring all cyclists to wear a helmet is more supported in America8 (79.3%) than in Europe22 (64.7%) and AsiaOceania6 (64.3%). Forbidding all drivers of motorized vehicles to use a hand-held mobile phone while driving is also one of the most supported measures, with about 80% of support in all regions (79.2%-81.3%).

Reference population: all road users, *not including Armenia, Kyrgyzstan, Uzbekistan (different methodology)

Figure 20: Support for policy measures, by region.

As for policy measures related to DUI of alcohol, the support for forbidding all novice drivers of motorized vehicles (license obtained less than 2 years ago) to drive with a blood alcohol concentration above 0.0 (zero tolerance) ranged from 73.4% in AsiaOceania6 to 78.3% in Europe22, and the support for installing alcohol interlocks for repeat drunk-driving offenders ranged from 76.4% in Europe22 to 82.4% in America8. Zero tolerance for DUI of alcohol for all drivers of motorized vehicles (65.8%-73.6%) and for all cyclists (62.5%-71.1%) were supported by less respondents. The support for these two measures is lower in Europe22 than in the other regions.

In all regions, women tend to be more supportive for road safety measures than men. Younger age categories are in general less in favour of policy measures than older age categories in most regions with the exception of speed limitations which are more supported by middle-aged respondents (25-34 and 35-44).

4.8 Infrastructure

The ESRA3 survey included one section with questions to assess the use of infrastructure and the correspondent perceived safety of that infrastructure by car drivers, moped riders and motorcyclists, cyclists, and pedestrians. Road users (at least a few days a year) were asked what type of roads they regularly use¹⁴ and how do they rate the infrastructure that they regularly use in terms of safety¹⁵.

4.8.1 Car drivers

Car drivers (at least a few days a year) were asked to select the types of roads that they regularly use and for each type of road selected they were asked how safe they feel while using it. Figure 21 shows the results per region for both questions (for national results and more statistical information see Table 27 and Table 28 in Appendix 7). The figure shows the percentage of car drivers that regularly use each type of road and the percentage that rated as safe each type of road that they use. The results in Figure 21 show that rural roads and roads connecting towns and villages are the most regularly used in Europe22 (mentioned by 75.2% car drivers), while in America8 the most used are thoroughfares and high-speed roads within cities (69.8%) and in AsiaOceania6 the most used are other streets and roads in urban areas (68.1%). As for the regional comparison, inter-city motorways and thoroughfares/high-speed roads within cities are more used in Europe22 and in America8 than in AsiaOceania6, rural roads and roads connecting towns and villages are more used in Europe22 than in the other regions, and other streets and roads in urban areas are more used in AsiaOceania6 than in the other regions.

*not including Armenia, Kyrgyzstan, Uzbekistan (different methodology); Reference population: (1) car drivers at least a few days a year, (2) car drivers at least a few days a year who regularly use the specific infrastructure

Figure 21: Use of infrastructure used by car drivers, by region.

Overall, inter-city motorways (considered safe by 57.4% to 66.1% of car drivers) and thoroughfares/high-speed roads within cities (53.0% to 59.8%) are perceived as safer than rural

¹⁴ "As a CAR DRIVER, what type of roads do you regularly use in [country]?" (similar questions were asked to moped riders and motorcyclists, cyclists, and pedestrians)

¹⁵ "As a CAR DRIVER, how would you rate the roads that you regularly use in terms of safety?" (similar questions were asked to moped riders and motorcyclists, cyclists, and pedestrians)

roads/roads connecting towns and villages (49.6% to 55.8%) and other streets/roads in urban areas (47.5% to 55.3%) in all the regions. Inter-city motorways are seen as less safe in America8 than in Europe22 and AsiaOceania6. On the contrary, rural roads/roads connecting towns and villages and other streets/roads in urban areas are considered safer in America8 than in the other regions.

4.8.2 Moped riders and motorcyclists

Figure 22 shows the results on the type of roads regularly used by moped riders and motorcyclists (at least a few days a year) and the correspondent perceived safety, per region (for national results and more statistical information see Table 29 and Table 30 in Appendix 7).

Results show large differences among regions in the percentages of moped riders and motorcyclists who regularly use thoroughfares and high-speed roads within cities: 64.3% in America8 (it is the most used), 50.6% in Europe22, and 36.4% in AsiaOceania6. Other streets and roads in urban areas are the most used in AsiaOceania6 (59.8%), while in Europe22 the percentage of moped riders and motorcyclists who use the listed types of roads are close to each other (50.6% to 54.7%).

Overall, the different types of roads are perceived as safer by motorcyclists and moped riders in America8 (58.5% to 68.0%) than in Europe22 (45.5% to 61.1%) and AsiaOceania6 (50.5% to 58.7%).

**not including Armenia, Kyrgyzstan, Uzbekistan (different methodology); Reference population: (1) motorcyclists and moped riders at least a few days a year, (2) motorcyclists and moped riders at least a few days a year who regularly use the specific infrastructure*

Figure 22: Use of infrastructure used by moped riders and motorcyclists and perceived safety, by region.

4.8.3 Cyclists

Figure 23 shows the results on the type of roads regularly used by cyclists (at least a few days a year) and the correspondent perceived safety, per region (for national results and more statistical information see Table 31 and Table 32 in Appendix 7).

Streets and roads in urban areas with cycle lanes are the most used type of road in all the regions: by 71.6% of cyclists in Europe22, by 70.3% in America8, and by 56.2% in AsiaOceania6. The percentage of cyclists who regularly use the other road types listed ranged from 25.4% to 47.2%. Rural roads and roads connecting towns and villages without or with cycle lanes are less used in America8 (25.4% and 36.5% respectively) than in Europe22 (33.5% and 44.5% respectively) and in AsiaOceania6 (36.4% and 43.5% respectively). On the other hand, streets and roads in urban areas without cycle lanes are more used in Europe22 (47.2%) than America8 (36.5%) and in AsiaOceania6 (40.1%).

Roads with cycle lanes are perceived as safer than roads without cycle lanes. This is valid for both rural roads and roads connecting towns and villages (% safe: 54.7%-62.7% with cycle lanes, 27.7%-45.8% without cycle lanes) and for streets and roads in urban areas (% safe: 55.6%-64.5% with cycle lanes, 19.8%-32.9% without cycle lanes). Roads without cycle lanes are considered safer in America8 than in the other regions.

**not including Armenia, Kyrgyzstan, Uzbekistan (different methodology); Reference population: (1) cyclists at least a few days a year, (2) cyclists at least a few days a year who regularly use the specific infrastructure*

Figure 23: Use of infrastructure used by cyclists and perceived safety, by region.

4.8.4 Pedestrians

Figure 24 shows the results on the type of roads regularly used by pedestrians (at least a few days a year) and the correspondent perceived safety, per region (for national results and more statistical information see Table 33 and Table 34 in Appendix 7).

Walking on streets and roads in urban areas with sidewalks is the type of road most regularly used by the pedestrians in all the regions: 88.9% in Europe22, 84.3% in America8, and 75.8% in AsiaOceania6. Between 34.7% to 36.5% of pedestrians regularly use streets and roads in urban areas without sidewalks. Rural roads and roads connecting towns and villages with sidewalks are used by 34.2% to 47.2% of the pedestrians and without sidewalks by 22.1% to 32.1%. Using rural roads with or without sidewalks is more common in AsiaOceania6 than in the other regions.

As for the perceived safety, roads with sidewalks are considered safer than roads without sidewalks in all the regions. This is valid for both rural roads and roads connecting towns and villages (% safe: 53.6%-64.7% with sidewalks, 28.7%-47.9% without sidewalks) and for streets and roads in urban areas (% safe: 60.4%-71.9% with sidewalks, 25.6%-32.6% without sidewalks). Rural roads and roads connecting towns and villages without sidewalks are considered safer in America8 than in the other regions.

*not including Armenia, Kyrgyzstan, Uzbekistan (different methodology); Reference population: (1) pedestrians at least a few days a year, (2) pedestrians at least a few days a year who regularly use the specific infrastructure

Figure 24: Use of infrastructure used by pedestrians and perceived safety, by region.

4.9 Limitations and points of attention for the future

For the data comparison and the next ESRA edition the following limitations and points of attention should be considered. For more information, see the ESRA3 methodology report (Meesmann & Wardenier, 2024).

Having a standardised methodology and sampling procedure in all participating countries is essential to obtain fully comparable and reliable data (e.g., De Leeuw et al., 2008). Although many efforts were done to achieve this in ESRA3, a few issues arose:

- In some countries it was not possible to aim for a sample size of at least 1000 respondents. This was the case in Armenia, Kyrgyzstan, Luxembourg, and Uzbekistan.
- In some countries another recruiting method had to be used as online panels were not available. Respondents were recruited on the street of different capital areas spread over the country (face to face recruitment) and invited to participate in a computer assisted personal interview (CAPI). This was in Armenia, Kyrgyzstan, and Uzbekistan. Due to the different methodology, the results of these three countries were not included in regional means as there are doubts about the comparability.
- In several countries the share of the oldest age group (65-74y) was underrepresented¹⁶. Also, in ESRA3 we worked with a maximum age of 74y, aiming for a national representative sample based on gender, six age groups and regional spread. In countries where this was not possible and where there was a reduced sample size of 500, the sample was reduced to three age groups with a maximum age of 44y. This was the case in Armenia, Kyrgyzstan and Uzbekistan.

Survey research is fraught with general response tendencies and biases, and this is especially true in cross-national studies (e.g., Lajunen et al., 1997; Tellis & Chandrasekaran, 2010). Road users of countries from Europe, America, Asia, or Oceania may have different cultural interpretations of the questions in the survey. Factors like social values, capabilities, personality, the role or status of a person, laws, road safety culture, and infrastructural differences vary among the different countries and may influence road users' responses (Pires et al., 2020; Van den Berghe et al., 2020). These biases might

¹⁶ This was the case in Brazil, Colombia, Peru, Thailand, Bosnia and Herzegovina, Kazakhstan, Türkiye, and Panama.

lead to erroneous conclusions (i.e., confusing differences in the social desirability with genuine differences in the measured trait).

Other limitations of self-declared data are the tendency of respondents to provide answers which present a favourable image of themselves (desirability bias), the misunderstanding of questions (e.g., questions with difficult words or long questions), or unintentional faulty answers due to memory errors (recall error) (Choi & Pak, 2005; Krosnick & Presser, 2010; Pires et al., 2020). To take desirability bias into account a social desirability scale was included in the ESRA questionnaire (for ESRA3 based on Nießen et al., 2019). This can help to correct for desirability-related bias by including this variable as controlling factor in, for example, regression models (Lajunen et al., 1997; Meesmann et al., 2020; Nießen et al., 2019).

In ESRA3, we saw an increase in the number of careless respondents. These are respondents that “fail to read or give sufficient attention to item content, resulting in data that may not accurately reflect respondents’ true levels of the constructs being measured (Meade & Craig 2012, Ward & Meade 2018)” (M. K. Ward & Meade, 2023, p. 578). We anticipated on this evolution by making our data cleaning procedure stricter and removing in ESRA3 all respondents that answered at least one of the two instructed response items (trick items) wrong. The experience in ESRA that careless responding is increasing in panels of market research agencies is a problematic evolution that should be monitored and taken care of also in the next ESRA editions.

Although the research agencies managing the online panels have made efforts to take a sample that is representative for each country’s population, selection-bias cannot be ruled out and therefore the representativeness for the national populations can be somewhat questioned. This selection-bias is mainly caused by the fact that not every person from the national population has an equal interest or intention to participate in such online panels. For example, certain groups are underrepresented in panels such as older people or people less familiar with the internet and smartphones. In turn, some groups are over-represented such as people who are more likely to participate in panels to earn extra money. The panel providers actively work to minimise this selection bias, but it cannot be excluded completely.

Finally, as highlighted in this section, some improvements are to be made when envisioning a fourth edition of the ESRA survey in 2026. A core set of questions will be retained in every survey allowing comparisons and the development of time series of road safety performance indicators.

5 Conclusions

5.1 Achievement of the initial aims and objectives

The initial aim of ESRA was to develop a system for gathering reliable and comparable information about people's attitudes towards road safety in several European countries. This objective has been achieved and the initial expectations have even been exceeded: ESRA has become a global initiative which already conducted surveys in 68 countries across six continents. The ESRA initiative has yielded a very rich dataset that is useful for understanding road safety risks and the effectiveness of policy measures. The ESRA data help to assess the national road safety situation and enables benchmarking in comparison to other countries or regions. In this way, the ESRA data are a solid foundation for national and international road safety monitoring systems. Furthermore, the ESRA partners indicated that the ESRA data are useful for their organization, and they use the data for dissemination activities. They are very satisfied with their return on investment for the resources their organization has spent on ESRA data collection.

5.2 The richness of the ESRA output

The key results of the ESRA3 survey were published through a series of reports including this report, a Methodology Report, 13 Thematic Reports on road safety topics (see Table 1) and 39 country fact sheets, in which national key results are compared to a regional mean. Scientific articles, national reports and many conference presentations are currently in progress. All common ESRA3 output has been peer-reviewed within the consortium, following a pre-defined quality control procedure. ESRA3 output can be freely consulted and downloaded at the ESRA website (www.esranet.eu).

Only a fraction of the available information has been included in this synthesis report. Of the many findings, some interesting results are presented below:

In relation to road safety in general:

- Being a pedestrian, travelling by car as a driver or as a passenger and using public transport are the most frequent modes of transport.
- Overall older road users report less the use of transport modes than younger ones, except for car driving where the youngest age category (25-34y) uses it the least.
- Riding an e-scooter, riding a moped or motorcycle, and cycling are perceived as the most unsafe modes of transport.
- The risk perception of the different unsafe traffic behaviours (distraction, DUI, fatigue and speeding) is the highest in Europe22, followed by America8 and the lowest in AsiaOceania6.
- There is a small difference between the different kinds of unsafe traffic behaviour (DUI, speeding, distraction and fatigue) regarding risk perception (considering it as being often a cause of a crash) in all regions.

In relation to behaviour of road users in traffic:

- In all regions, the most frequently declared unsafe traffic behaviour of car drivers is speeding and talking on a hands-free mobile phone.
- About half of the car passengers in America8 and AsiaOceania6 report not wearing the seatbelt in the back seat, in Europe22 this was about one third.
- Two to three out of ten of the car drivers reported using the phone while driving, to call hand-held or to read a message or check social media/news.
- In America8 and AsiaOceania6 three out of ten of the car drivers who transports children under 150cm reported not using a child restraint system, in Europe22 about two out of ten.
- Male car drivers report more unsafe traffic behaviour than female drivers.
- Ride without a helmet is the most common reported behaviour among moped riders and motorcyclists in AsiaOceania6. In Europe22 and America8 speeding is the most declared unsafe behaviour.

- Cycling without a helmet, which is allowed in most of the countries, is the most declared unsafe traffic behaviour in Europe²² and AsiaOceania⁶ among cyclists. In America⁸ the most common unsafe behaviour for cyclists is cycling while listening to music through headphones.
- Among pedestrians crossing the road at places other than at a nearby pedestrian crossing and distraction by the phone are the most common unsafe behaviours in all regions.
- Riding without a helmet and riding on the pedestrian pavement/sidewalk is the most common reported unsafe traffic behaviour among e-scooter riders in all regions.
- Talking on a handsfree mobile phone is the most accepted unsafe traffic behaviour for car drivers. The second most accepted behaviour is speeding on motorways and outside built-up areas.
- The acceptability of unsafe traffic behaviours for car drivers is overall low, with less than 5% of the respondents thinking it is acceptable, except for handsfree calling and speeding.
- People think that others find risky behaviour in traffic more acceptable than they do themselves.
- In most regions younger age categories systematically report higher social acceptability and personal acceptability of unsafe traffic behaviour than older age categories.
- The perceived behaviour control (perceived ability to control the car during the unsafe behaviour) is the highest for speeding compared to alcohol or distraction by phone.
- In all regions, men have more risky road safety attitudes compared to women.

In relation to policy measures and enforcement:

- The perceived likelihood of being checked as a car driver is the highest in AsiaOceania⁶, followed by America⁸, and the lowest in Europe²². This is the case for respecting speed limits, wearing the seatbelt and being checked for driving under the influence of alcohol.
- In all regions, the reported likelihood of being checked is the highest for respecting the speed limits and for wearing the seatbelt.
- Male drivers and younger drivers report a higher likelihood of being checked for traffic violations than respectively female drivers and older drivers.
- About one out of five of the car drivers was checked by the police for driving under the influence of alcohol in the past 12 months in all regions.
- Overall, the three most supported policy measures are requiring cyclists under the age of 12 to wear a helmet, forbidding all drivers of motorized vehicles to use a hand-held mobile phone while driving and installing an alcohol 'interlock' for drivers who have been caught drunk driving on more than one occasion. 76% of the respondents or more are in favour of these measures in all regions.
- The least supported policy measures are those related to speeding (limiting speed limit to 80 km/h on all rural roads without a median strip and limiting the speed limit to 30 km/h in all built-up areas (except main thoroughfares)).

In relation to infrastructure:

- In Europe²² car drivers use the most rural roads and roads connecting town and villages and in America⁸ thoroughfares and high-speed roads within cities. In AsiaOceania⁶ the most used infrastructure by car drivers is other streets and roads in urban areas.
- Both inter-city motorways and thoroughfares/high-speed roads within cities are perceived as safer by car drivers than rural roads/roads connecting towns and villages and other streets/roads in urban areas in all the regions.
- Cyclists use the most streets and roads in urban areas with cycle lanes of all types of infrastructure.
- Roads with cycle lanes are perceived as safer than roads without cycle lanes, both on rural roads and urban roads in all regions.

- Streets and roads in urban areas with sidewalks are the infrastructure that is used the most by pedestrians in all regions.
- Pedestrians perceive roads with sidewalks safer than roads without sidewalks (both rural and urban) in all the regions.

As shown in this report the ESRA3 survey provides a unique data set of road users' opinions, attitudes, and behaviour in relation to road safety. The total sample size consists of 37093 road users from 39 countries. The information is recent (2023), reliable and comparable across countries. Therefore, the results can form the basis for benchmarking road safety culture in a regional and global perspective.

5.3 Towards ESRA4

In ESRA4, the overall methodological approach that was developed and implemented in the previous editions will be maintained. In each participating country ESRA4 will target again a representative sample of the national adult population (18-74 years old). Many questions will remain the same to allow for observing trends over time. The questionnaire will be conducted in the national language of the country (in countries with several languages, the main ones will be used).

The data collection will be organized between May and June 2026 and undertaken by survey and polling agencies via online panels, under the supervision of Vias institute. All data collected will be centrally stored and processed. Small deviations from the overall methodology (sample size, survey method) will be considered in countries where the standard methodology cannot be applied.

Organisations interested in joining ESRA and becoming a national ESRA partner can contact the ESRA Coordination Team at ESRA@vias.be.

Appendix 1: ESRA3 Questionnaire

Introduction

In this questionnaire, we ask you some questions about your experience with, and your attitudes towards traffic and road safety. When responding to a question, please answer in relation to the traffic and road safety situation in [COUNTRY]. There are no right or wrong answers; what matters is your own experience and perception.

Socio-demographic information

- Q1)** In which country do you live? _____
- Q2)** Are you ... male – female - other
- Q3)** How old are you (in years)? [Drop down menu]
- Q4_1)** Are you currently a student? yes - no
- Q4_2)** What is the highest qualification or educational certificate which you want to achieve?
primary education - secondary education - bachelor's degree or similar - master's degree or higher
- Q4_3)** What is the highest qualification or educational certificate that you have obtained? none -
primary education - secondary education - bachelor's degree or similar - master's degree or higher
- Q5)** Which of the descriptions comes closest to how you feel about your household's income nowadays? living comfortably on present income - coping on present income - finding it difficult on present income - finding it very difficult on present income
- Q6a)** Is the car you regularly drive equipped with seatbelts in the front seat? yes – no
Only asked to LMIC countries.
- Q6b)** Is the car you regularly drive equipped with seatbelts in the back seat? yes - no
Only asked to LMIC countries.
- Q7)** Are you using a carsharing organization (e.g., poppy or cambio¹⁷)? yes – no
Only asked to HIC/UMIC countries.
- Q8)** Do you have to drive or ride a vehicle during your main professional activity? yes, I transport mainly other person(s) (e.g., taxi, bus, rickshaw, ...) - yes, I transport mainly goods (e.g., truck, courier, food delivery,...) - yes, I transport mainly myself (e.g., visiting patients, salesperson,...) - no, I drive or ride a vehicle only for commuting or private reasons
- Q9)** Which phrase best describes the area where you live? a farm or home in the countryside - a country village - a town or a small city - the suburbs or outskirts of a big city - a big city
- Q10)** In which region do you live? [List of regions per country]
- Q11a)** How far do you live from the nearest stop of public transport? less than 500 metres - between 500 metres and 1 kilometre - more than 1 kilometre
- Q11b)** What is the frequency of your nearest public transport? at least 3 times per hour - 1 or 2 times per hour - less than 1 time per hour

Mobility & exposure

¹⁷ The examples in brackets were adapted to national context.

Q12) During the past 12 months, how often did you use each of the following transport modes in [country]? How often did you ...? at least 4 days a week - 1 to 3 days a week - a few days a month - a few days a year - never

Items (random order): take the train - take the bus or minibus - take the tram/streetcar - take the subway, underground, metro - take a plane - take a ship/boat or ferry - be a passenger on non-motorized individual public transport mode (e.g., bike taxi, animal carriages,...) - be a passenger on motorized individual public transport mode (e.g., car-taxi, moto-taxi, tuk-tuk, auto rickshaw, songthaew,...) - walk or run minimum 200m down the street - cycle (non-electric) - cycle on an electric bicycle / e-bike / pedelec - drive a moped (≤ 50 cc or ≤ 4 kW) - drive a motorcycle (> 50 cc or > 4 kW) - ride an e-scooter (electric-kick style scooter) - drive a car (non-electric or non-hybrid) - drive a hybrid or electric car - be a passenger in a car - be a passenger on a moped or motorcycle - use another transport mode

Q13) Over the last 30 days, have you transported a child (<18 years of age) in a car? yes - no

Items (random order): under 150cm - above 150cm¹⁸

Self-declared safe and unsafe behaviour in traffic

Q14_1a) Over the last 30 days, how often did you as a CAR DRIVER ...? You can indicate your answer on a scale from 1 to 5, where 1 is "never" and 5 is "(almost) always". The numbers in between can be used to refine your response.

Binary variable for most items: at least once (2-5) - never (1); only exception: items on protective systems: always wear/transport (1) – not always wear/transport (2-5)

Items (random order):

- drive when you may have been over the legal limit for drinking and driving
- drive after drinking alcohol
- drive within 1 hour after taking drugs (other than prescribed or over the counter medication)
- drive within 2 hours after taking medication that may affect your driving ability
- drive faster than the speed limit inside built-up areas
- drive faster than the speed limit outside built-up areas (except motorways/freeways)
- drive too fast for the road/traffic conditions at the time (e.g., poor visibility, dense traffic, presence of vulnerable road users)
- drive faster than the speed limit on motorways/freeways
- drive without wearing your seatbelt
- transport children under 150cm¹⁹ without using child restraint systems (e.g., child safety seat, cushion)
- transport children above 150cm²⁰ without wearing their seatbelt
- talk on a hand-held mobile phone while driving
- talk on a hands-free mobile phone while driving
- read a message or check social media/news while driving
- drive when you were so sleepy that you had trouble keeping your eyes open

Q14_1b_1) You said that you have driven a car when you may have been over the legal limit for drinking and driving. Was this ...? You can indicate multiple answers: in the week during daytime - in the week during night-time - in the weekend during daytime - in the weekend during night-time - on motorways - on urban roads - on rural roads
Only asked to HIC/UMIC countries.

Q14_1b_2) You said that you have driven a car within 1 hour after taking drugs (other than prescribed or over the counter medication). Was this ...? You can indicate multiple answers: cannabis - cocaine - amphetamines (e.g., speed, extasy) - illicit opiates (e.g., morphine, codeine; not prescribed as medication) - other

Q14_1b_3) You said that you have driven a car within 2 hours after taking medication that may affect your driving ability. Was this ...? You can indicate multiple answers²¹: antihistamines and/or cough medicines (such as Claritin, Allegra, Benadryl) - antidepressants (such as Prozac, Zoloft, Wellbutrin) - prescription pain medicines (such as Tylenol with codeine, OxyContin, Percocet, Vicodin/hydrocodone) - muscle relaxants (such as Soma, Flexeril) - sleep aids, Barbiturates, or Benzodiazapines

¹⁸ This question was adapted to national legal regulation.

¹⁹ This question was adapted to national legal regulation.

²⁰ This question was adapted to national legal regulation.

²¹ The examples in brackets were adapted to national context.

(such as Ambien, Lunesta, phenobarbital, Xanax, Valium, Ativan) - amphetamines (such as Adderall, Dexedrine, phentermine) - other

Q14_2) Over the last 30 days, how often did you as a CAR PASSENGER ...? You can indicate your answer on a scale from 1 to 5, where 1 is "never" and 5 is "(almost) always". The numbers in between can be used to refine your response.

Binary variable for most items: always wear/transport (1) – not always wear/transport (2-5)

Items (random order):

- travel without wearing your seatbelt in the back seat
- travel without wearing your seatbelt in the front seat

Q14_3) Over the last 30 days, how often did you as a MOPED RIDER or MOTORCYCLIST ...? You can indicate your answer on a scale from 1 to 5, where 1 is "never" and 5 is "(almost) always". The numbers in between can be used to refine your response.

Binary variable for most items: at least once (2-5) - never (1); only exception: items on protective systems: always wear/transport (1) – not always wear/transport (2-5)

Items (random order):

- ride when you may have been over the legal limit for drinking and driving
- ride faster than the speed limit outside built-up areas (except motorways/freeways)
- not wear a helmet on a moped or motorcycle
- read a message or check social media/news while riding
- ride within 1 hour after taking drugs (other than prescribed or over the counter medication)
- ride too fast for the road/traffic conditions at the time (e.g., poor visibility, dense traffic, presence of vulnerable road users) - Only asked to LMIC countries.
- ride a motorcycle with more than 1 passenger

Q14_4) Over the last 30 days, how often did you as a CYCLIST ...? You can indicate your answer on a scale from 1 to 5, where 1 is "never" and 5 is "(almost) always". The numbers in between can be used to refine your response.

Binary variable for most items: at least once (2-5) - never (1); only exception: items on protective systems: always wear/transport (1) – not always wear/transport (2-5)

Items (random order):

- cycle when you think you may have had too much to drink
- cycle without a helmet
- cycle while listening to music through headphones
- read a message or check social media/news while cycling
- cycle within 1 hour after taking drugs (other than prescribed or over the counter medication)
- cross the road when a traffic light is red

Q14_5) Over the last 30 days, how often did you as a PEDESTRIAN ...? You can indicate your answer on a scale from 1 to 5, where 1 is "never" and 5 is "(almost) always". The numbers in between can be used to refine your response.

Binary variable for most items: at least once (2-5) - never (1); only exception: items on protective systems: always wear/transport (1) – not always wear/transport (2-5)

Items (random order):

- listen to music through headphones while walking down the street
- walk down the street when you think you may have had too much to drink
- read a message or check social media/news while walking down the street
- text a message while walking down the street
- cross the road when a pedestrian light is red
- cross the road at places other than at a nearby (distance less than 30m²²) pedestrian crossing

Q14_6) Over the last 30 days, how often did you as RIDER OF AN E-SCOOTER (electric-kick style scooter) ...? You can indicate your answer on a scale from 1 to 5, where 1 is "never" and 5 is "(almost) always". The numbers in between can be used to refine your response.

Binary variable for most items: at least once (2-5) - never (1); only exception: items on protective systems: always wear/transport (1) – not always wear/transport (2-5)

Only asked to HIC/UMIC countries.

²² This question was adapted to national legal regulation.

Items (random order):

- ride with more than 1 person on board
- ride when you think you may have had too much to drink
- cross the road when a traffic light is red
- ride on pedestrian pavement/sidewalk
- ride without a helmet

Acceptability of safe and unsafe traffic behaviour

Q15) Where you live, how acceptable would most other people say it is for a CAR DRIVER to?

You can indicate your answer on a scale from 1 to 5, where 1 is "unacceptable" and 5 is "acceptable". The numbers in between can be used to refine your response.

Binary variable: acceptable (4-5) – unacceptable/neutral (1-3)

Items (random order):

- drive when he/she may be over the legal limit for drinking and driving
- drive faster than the speed limit outside built-up areas (except motorways/freeways)
- drive without wearing the seatbelt
- talk on a hand-held mobile phone while driving
- read a message or check social media/news while driving

Q16_1) How acceptable do you, personally, feel it is for a CAR DRIVER to ...? You can indicate your answer on a scale from 1 to 5, where 1 is "unacceptable" and 5 is "acceptable". The numbers in between can be used to refine your response.

Binary variable: acceptable (4-5) – unacceptable/neutral (1-3)

Items (random order; instructed response item (trick item) as last item):

- drive when he/she may be over the legal limit for drinking and driving
- drive within 1 hour after taking drugs (other than prescribed or over the counter medication)
- drive within 2 hours after taking a medication that may affect the driving ability
- drive faster than the speed limit inside built-up areas
- drive faster than the speed limit outside built-up areas (except motorways/freeways)
- drive too fast for the road/traffic conditions at the time (e.g., poor visibility, dense traffic, presence of vulnerable road users)
- drive faster than the speed limit on motorways/freeways
- drive without wearing the seatbelt
- transport children in the car without securing them (child's car seat, seatbelt, etc.)
- talk on a hand-held mobile phone while driving
- talk on a hands-free mobile phone while driving
- read a message or check social media/news while driving
- drive when he/she is so sleepy that he/she has trouble keeping their eyes open
- Please, select the answer option number 5 "acceptable". (Instructed response item (trick item))

Q16_2) How acceptable do you, personally, feel it is for a MOPED RIDER or MOTORCYCLIST to ...?

You can indicate your answer on a scale from 1 to 5, where 1 is "unacceptable" and 5 is "acceptable". The numbers in between can be used to refine your response.

Binary variable: acceptable (4-5) – unacceptable/neutral (1-3)

Items (random order):

- ride when he/she may have been over the legal limit for drinking and driving
- ride faster than the speed limit outside built-up areas (except motorways/freeways)
- not wear a helmet on a moped or motorcycle
- read a message or check social media/news while riding
- ride a motorcycle with more than 1 passenger – Only asked to LMIC countries.

Q16_3) How acceptable do you, personally, feel it is for a CYCLIST to ...? You can indicate your answer on a scale from 1 to 5, where 1 is "unacceptable" and 5 is "acceptable". The numbers in between can be used to refine your response.

Binary variable: acceptable (4-5) – unacceptable/neutral (1-3)

Items (random order):

- cycle when he/she may have had too much to drink
- cycle without a helmet
- read a message or check social media/news while cycling
- cross the road when a traffic light is red

Q16_4) How acceptable do you, personally, feel it is for a PEDESTRIAN to ...? You can indicate your answer on a scale from 1 to 5, where 1 is "unacceptable" and 5 is "acceptable". The numbers in between can be used to refine your response.

Binary variable: acceptable (4-5) – unacceptable/neutral (1-3)

Items (random order):

- walk down the street when he/she may have had too much to drink
- read a message or check social media/news while walking down the street
- cross the road when a pedestrian light is red

Attitudes towards safe and unsafe behaviour in traffic

Q17) To what extent do you agree with each of the following statements? You can indicate your answer on a scale from 1 to 5, where 1 is "disagree" and 5 is "agree". The numbers in between can be used to refine your response.

Binary variable: agree (4-5) – disagree/neutral (1-3)

Items (random order):

Behaviour believes & attitudes

- For short trips, one can risk driving under the influence of alcohol.
- I have to drive fast; otherwise, I have the impression of losing time.
- Respecting speed limits is boring or dull.
- Motorized vehicles should always give way to pedestrians or cyclists.
- I use a mobile phone while driving, because I always want to be available.
- To save time, I often use a mobile phone while driving.

Perceived behaviour control = self-efficacy

- I trust myself to drive after drinking a small amount of alcohol (e.g., one glass of wine or one pint of beer).
- I have the ability to drive when I am a little drunk after a party.
- I am able to drive after drinking a large amount of alcohol (e.g., a bottle of wine).
- I trust myself when I drive significantly faster than the speed limit.
- I have the ability to drive significantly faster than the speed limit.
- I am able to drive fast through a sharp curve.
- I trust myself when I check messages on the mobile phone while driving.
- I have the ability to write a message on the mobile phone while driving.
- I am able to talk on a hand-held mobile phone while driving.

Habits

- I often drive after drinking alcohol.
- I often drive faster than the speed limit.
- I often use my mobile phone while driving.

Intention

- I intend not to drive after drinking alcohol in the next 30 days.
- I intend to respect speed limits in the next 30 days.
- I intend not to use my mobile phone while driving in the next 30 days.

Subjective safety & risk perception

Q18) How safe or unsafe do you feel when using the following transport modes in [country]?

You can indicate your answer on a scale from 0 to 10, where 0 is "very unsafe" and 10 is "very safe". The numbers in between can be used to refine your response.

Items (random) = Items indicated by the respondent in Q12 are displayed.

Q19) How often do you think each of the following factors is the cause of a road crash involving a car? You can indicate your answer on a scale from 1 to 6, where 1 is "never" and 6 is "(almost) always". The numbers in between can be used to refine your response.

Binary variable: often/frequently (4-6) – not that often/not frequently (1-3)

Items (random order):

- driving after drinking alcohol
- driving within 1 hour after taking drugs (other than prescribed or over the counter medication)
- driving faster than the speed limit
- using a hand-held mobile phone while driving
- using a hands-free mobile phone while driving
- inattentiveness or daydreaming while driving
- driving while tired

Support for policy measures

Q20) **Do you oppose or support a legal obligation ...?** You can indicate your answer on a scale from 1 to 5, where 1 is "oppose" and 5 is "support". The numbers in between can be used to refine your response.

Binary variable: support (4-5) – oppose/neutral (1-3)

Items for all countries (random order):

- forbidding all drivers of motorized vehicles to drive with a blood alcohol concentration above 0.0 ‰ (zero tolerance)
- forbidding all drivers of motorized vehicles to use a hand-held mobile phone while driving
- limiting the speed limit to 30 km/h in all built-up areas (except on main thoroughfares)
- requiring all cyclists to wear a helmet
- limiting the speed limit to a maximum of 80 km/h on all rural roads without a median strip
- forbidding all novice drivers of motorized vehicles (license obtained less than 2 years ago) to drive with a blood alcohol concentration above 0.0 ‰ (zero tolerance)

Items only for HIC/UMIC countries (random order):

- installing an alcohol 'interlock' for drivers who have been caught drunk driving on more than one occasion (technology that won't let the car start if the driver's alcohol level is over a certain limit)
- requiring cyclists under the age of 12 to wear a helmet
- forbidding all cyclists to ride with a blood alcohol concentration above 0,0‰ (zero tolerance)

Items only for LMIC countries (random order):

- forbidding all professional drivers of motorized vehicles (e.g., taxis, vans, trucks, buses, ...) to drive with a blood alcohol concentration above 0.0 ‰ (zero tolerance)
- requiring all moped and motorcycle riders and passengers to wear a helmet
- requiring all car drivers and passengers (front- and back seat) to wear a seatbelt
- making liability insurance mandatory for owners of cars

Q21) **Please think of the policy measure: "... " and indicate if you agree or disagree with the following statements about it. This policy measure would ...?** Disagree – agree

Random selection of one of the first 4 items in Q20 per respondent. All first 4 items in Q20 are be asked equally often in each country.

Items (random order):

- reduce the number of road crashes and injuries
- increase the safety feeling on the streets
- have negative side effects
- restrict people's individual freedom
- reduce the privacy of people
- limit people's mobility
- lead to discrimination
- be fair
- be expensive for people
- be easy to implement
- be difficult to enforce by the police
- be a burden for people
- be an unjustifiable intervention by the state
- be supported by many of my friends

Enforcement

Q22) **On a typical journey, how likely is it that you (as a car driver) will be checked by the police (including cameras or radars) for ...?** You can indicate your answer on a scale from 1 to 7, where 1 is "very unlikely" and 7 is "very likely". The numbers in between can be used to refine your response.

Binary variable: likely (5-7) – unlikely/neutral (1-4)

Items (random order):

- alcohol, in other words, being subjected to a Breathalyser test
- the use of illegal drugs
- respecting the speed limits
- wearing your seatbelt
- the use of hand-held mobile phone to talk or text while driving

Q23_1) **In the past 12 months, how many times have you been checked by the police for using alcohol while driving a car (i.e., being subjected to a Breathalyser test)?** Never – 1 time – at least 2 times – Binary variable: at least once – never

- Q23_2)** In the past 12 months, how many times have you been checked by the police for using drugs (other than prescribed or over the counter medication) while driving a car? Never – 1 time – at least 2 times – Binary variable: at least once – never

Involvement in road crashes

The following questions focus on road crashes. With road crashes, we mean any collision involving at least one road vehicle (e.g., car, motorcycle, or bicycle) in motion on a public or private road to which the public has right of access. Furthermore, these crashes result in material damage, injury, or death. Collisions include those between road vehicles, road vehicles and pedestrians, road vehicles and animals or fixed obstacles, road and rail vehicles, and one road vehicle alone.

- Q24a)** In the past 12 months, have you personally been involved in a road crash where at least one person was injured (light, severe or fatal crashes)? Yes – no
- Q24b)** Please indicate the transport mode(s) YOU were using at the time of these crashes. You can indicate multiple answers: as a car driver – as a car passenger – as a moped or motorcycle rider – as a moped or motorcycle passenger – as a cyclist – as a pedestrian – as a rider of an e-scooter (electric-kick style scooter) – other

Infrastructure

- Q25_1_a)** As a CAR DRIVER, what type of roads do you regularly use in [country]? You can indicate multiple answers: inter-city motorways – thoroughfares and high-speed roads within cities – rural roads and roads connecting towns and villages – other streets and roads in urban areas

- Q25_1_b)** As a CAR DRIVER, how would you rate the roads that you regularly use in terms of safety? You can indicate your answer on a scale from 1 to 7, where 1 is “very unsafe” and 7 is “very safe”. The numbers in between can be used to refine your response.

Binary variable: safe (5-7) – unsafe/neutral (1-4)

Items (random order):

- inter-city motorways
- thoroughfares and high-speed roads within cities
- rural roads and roads connecting towns and villages
- other streets and roads in urban areas

- Q25_2_a)** As a MOPED RIDER or MOTORCYCLIST, what type of roads do you regularly use in [country]? You can indicate multiple answers: thoroughfares and high-speed roads within cities – rural roads and roads connecting towns and villages – other streets and roads in urban areas

- Q25_2_b)** As a MOPED RIDER or MOTORCYCLIST, how would you rate the roads that you regularly use in terms of safety? You can indicate your answer on a scale from 1 to 7, where 1 is “very unsafe” and 7 is “very safe”. The numbers in between can be used to refine your response.

Binary variable: safe (5-7) – unsafe/neutral (1-4)

Items (random order):

- thoroughfares and high-speed roads within cities
- rural roads and roads connecting towns and villages
- other streets and roads in urban areas

- Q25_3_a)** As a CYCLIST, what type of roads/cycle lanes do you regularly use in [country]? You can indicate multiple answers: rural roads and roads connecting towns and villages with cycle lanes – rural roads and roads connecting towns and villages without cycle lanes – streets and roads in urban areas with cycle lanes – streets and roads in urban areas without cycle lanes

- Q25_3_b)** As a CYCLIST, how would you rate the roads/cycle lanes that you regularly use in terms of safety? You can indicate your answer on a scale from 1 to 7, where 1 is “very unsafe” and 7 is “very safe”. The numbers in between can be used to refine your response.

Binary variable: safe (5-7) – unsafe/neutral (1-4)

Items (random order):

- rural roads and roads connecting towns and villages with cycle lanes
- rural roads and roads connecting towns and villages without cycle lanes

- streets and roads in urban areas with cycle lanes
- streets and roads in urban areas without cycle lanes

Q25_4_a) As a PEDESTRIAN, what type of roads/sidewalks do you regularly use in [country]? You can indicate multiple answers: rural roads and roads connecting towns and villages with sidewalks – rural roads and roads connecting towns and villages without sidewalks – streets and roads in urban areas with sidewalks – streets and roads in urban areas without sidewalks

Q25_4_b) As a PEDESTRIAN, how would you rate the roads/sidewalks that you regularly use in terms of safety? You can indicate your answer on a scale from 1 to 7, where 1 is “very unsafe” and 7 is “very safe”. The numbers in between can be used to refine your response.

Binary variable: safe (5-7) – unsafe/neutral (1-4)

Items (random order):

- rural roads and roads connecting towns and villages with sidewalks
- rural roads and roads connecting towns and villages without sidewalks
- streets and roads in urban areas with sidewalks
- streets and roads in urban areas without sidewalks

Social desirability scale

Introduction: The survey is almost finished. Some of the following questions²³ have nothing to do with road safety, but they are important background information. There are no good or bad answers.

Q26) To what extent do you agree with each of the following statements? You can indicate your answer on a scale from 1 to 5, where 1 is “disagree” and 5 is “agree”. The numbers in between can be used to refine your response.

Items (random order; instructed response item (trick item) as last item):

- In an argument, I always remain objective and stick to the facts.
- Even if I am feeling stressed, I am always friendly and polite to others.
- When talking to someone, I always listen carefully to what the other person says.
- It has happened that I have taken advantage of someone in the past.
- I have occasionally thrown litter away in the countryside or on to the road.
- Sometimes I only help people if I expect to get something in return.
- Please, select the answer option number 5 “agree”. (Instructed response item (trick item))

Closing comment: Thank you for your contribution!

²³ Q26 is asked together with some last questions on sociodemographic information, which have already been listed in the beginning of the questionnaire.

Appendix 2: ESRA3 weights

The following weights were used to calculate representative means on national and regional level. They are based on UN population statistics (United Nations Statistics Division, 2023). The weighting took into account small corrections with respect to national representativeness of the sample based on gender and six age groups (18-24y, 25-34y, 35-44y, 45-54y, 55-64y, 65-74y). For the regions, the weighting also took into account the population size of each country in the total set of countries from this region.

Individual country weight	Individual country weight is a weighting factor based on the gender*6 age groups (18-24y, 25-34y, 35-44y, 45-54y, 55-64y, 65-74y) distribution in a country as retrieved from the UN population statistics.
Europe22 weight	European weighting factor based on all 22 European countries participating in ESRA3, considering individual country weight and population size of the country as retrieved from the UN population statistics.
America8 weight	American weighting factor based on all 8 North and Latin American countries participating in ESRA3, considering individual country weight and population size of the country as retrieved from the UN population statistics.
AsiaOceania6 weight	Asian and Oceanian weighting factor based on the 6 Asian and Oceanian countries participating in ESRA3 with data collected through online panel (Australia, Israel, Japan, Kazakhstan, Thailand, Türkiye - Armenia, Kyrgyzstan, and Uzbekistan were not included due to different methodology in data collection – face-to-face CAPI), considering individual country weight and population size of the country as retrieved from the UN population statistics.

Appendix 3: Summary of ESRA3 fieldwork per country

Appendix 4: Overview of subgroups per main road user type

Q12) During the past 12 months, how often did you use each of the following transport modes in [country]? How often did you ...? at least 4 days a week - 1 to 3 days a week - a few days a month - a few days a year - never

User of public transport

- take the train
- take the bus or minibus
- take the tram/streetcar
- take the subway, underground, metro
- take a plane
- take a ship/boat or ferry
- be a passenger on non-motorized individual public transport mode (e.g., bike taxi, animal carriages,...)
- be a passenger on motorized individual public transport mode (e.g., car-taxi, moto-taxi, tuk-tuk, auto rickshaw, songthaew,...)

Car as a driver

- drive a car (non-electric or non-hybrid)
- drive a hybrid or electric car

Car as a passenger

- be a passenger in a car

Motorcyclist/ moped rider

- drive a moped (≤ 50 cc or ≤ 4 kW)
- drive a motorcycle (> 50 cc or > 4 kW)

Cyclist

- cycle (non-electric)
- cycle on an electric bicycle / e-bike / pedelec

E-scooter

- ride an e-scooter (electric-kick style scooter)

Pedestrian

- walk or run minimum 200m down the street

Appendix 5: Sample size per main road user group type

Table 4: Weighted sample size by region and country.

Country	All road users	car drivers, at least a few days a year	car drivers, at least a few days a month	motorcyclists/ moped riders, at least a few days a month	cyclists, at least a few days a month	pedestrians, at least a few days a month

Note. (1) Reference population: all road users. (2) Unweighted sample for countries, weighted for region. (3) * Armenia, Kyrgyzstan, Uzbekistan not included due to different methodology (face-to-face CAPI).

Appendix 7: Key results from ESRA3 per country

This appendix provides detailed information on the results presented in Chapter 4 'Key results from the ESRA3 survey'. National values and more detailed information on the significant differences between regional means are shown. In this appendix the following tables are presented:

Table 6: Use of transport modes, by country and region.	65
Table 7: Self-declared behaviour as a car driver, by country and region – DUI and speeding.....	66
Table 8: Self-declared behaviour as a car driver, by country and region – distraction and fatigue.	67
Table 9: Self-declared behaviour as a car driver, by country and region – protective systems.....	68
Table 10: Self-declared behaviour as a car passenger, by country and region.....	69
Table 11: Self-declared behaviour as a motorcyclist or moped rider, by country and region.	70
Table 12: Self-declared behaviour as a cyclist, by country and region.....	71
Table 13: Self-declared behaviour as a pedestrian, by country and region.....	72
Table 14: Self-declared behaviour as a e-scooter rider, by country and region.....	73
Table 15: Personal acceptability of car driver's unsafe behaviours, by country and region – DUI and speeding.	74
Table 16: Personal acceptability of car driver's unsafe behaviours, by country and region – distraction, protective systems, and fatigue.....	75
Table 17: Social acceptability of car driver's unsafe behaviours, by country and region.....	76
Table 18: Personal acceptability of moped riders and motorcyclist's unsafe traffic behaviours, by country and region.....	77
Table 19: Personal acceptability of cyclist's unsafe traffic behaviours, by country and region.....	78
Table 20: Personal acceptability of pedestrian's unsafe traffic behaviours, by country and region.	79
Table 21: Composite mean scores for attitudes and perceived behaviour control: DUI (alcohol), distraction (mobile phone), and speeding, by country and region.....	80
Table 22: Subjective safety feeling, by country and region.	81
Table 23: Risk perception - causes of road car crash, by country and region.	82
Table 24: Enforcement perception, by country and region.....	83
Table 25: Police checks for using alcohol and for the use of drugs, by country and region.	84
Table 26: Support for policy measures, by country and region.....	85
Table 27: Use of infrastructure used by car drivers, by country and region.....	86
Table 28: Perceived safety of infrastructure used by car drivers, by country and region.....	87
Table 29: Use of infrastructure used by moped riders and motorcyclists, by country and region.	88
Table 30: Perceived safety of infrastructure used by moped riders and motorcyclists, by country and region.....	89
Table 31: Use of infrastructure used by cyclists, by country and region.	90
Table 32: Perceived safety of infrastructure used by cyclists, by country and region.....	91
Table 33: Use of infrastructure used by pedestrians, by country and region.	92
Table 34: Perceived safety of infrastructure used by pedestrians, by country and region.	93

The tables show all national values. The last five lines in the tables are dedicated to the regional means and provide additional information on the significant differences between the regions. Each superscript letter denotes a region whose proportions do not differ significantly from each other at the 0.01 level. In other words, if two regions have the same superscript letter their means do not differ significantly from each other, but if they have different letters, their values are significantly different.

Statistical analysis

For nominal data, the Chi-square Test of Independence was used to assess if the answers depend significantly on the region. Pairwise comparisons were used to identify the pairs of regions that differ significantly, at a significance level of 1%. The strength of the association was assessed through the Cramer's V coefficient. The following thresholds were considered to classify the strength of associations (Cohen, 1988): small=0.07, medium=0.21, large=0.35.

For continuous variables (safety feeling and attitudes composite scores), ANOVA was used for region comparisons. Pairwise comparisons were performed with Tukey HSD test, considering a significance

level of 1%. The strength of the differences was assessed through eta squared (Cohen, 1988): 0.01 indicates a small Effect, 0.06 indicates a medium Effect, and 0.14 indicates a large effect.

SPSS 29.0 (IBM Corp., 2022) and R 4.3.1 (R Core Team, 2023) were used for the data processing and data analysis.

Table 6: Use of transport modes, by country and region (% at least a few days a month).
